Preface

Computers today invade almost every aspect of our lives and are used in many different ways, education being no exception. This, of course, was not always the case, and computers today are used in many different ways from the calculating machines from which they evolved. The *stored-program electronic digital computer* first appeared in the 1940s, but computing goes back much further than this and can be traced to earlier technologies including the abacus, Antikythera mechanism (ancient Greek analog computer), Napier's bones (logarithms), and Babbage's difference engine that performed many of the mathematical tasks now performed by computers. From a machine designed to perform calculations, the computer soon evolved into an information processing and communications machine that became indispensable around the world.

University courses in computing began in many countries in the Departments of Mathematics in the late 1940s. The question whether *Computer Science* was a branch of science, a branch of engineering, or whether it was something else entirely unique was long discussed, and it was not until the mid-1960s that university courses in Computer Science as a separate discipline became widely available. Largely due to increased computerization of government departments and the growing computing needs of businesses, in the 1970s university courses in *Business Computing* began to appear. These soon evolved into what we now call *Information Systems*. Today, university courses make use of computers in many ways in both teaching and in research.

It was in the 1970s that school computing began around the world when a small number of schools in some countries began using shared minicomputers along with punched cards for teaching programming in conjunction with facilities at local universities. This mostly related to mathematics, and the teachers involved were typically mathematics or science teachers who had done some computer programming in their university degree courses. The arrival of relatively low cost microcomputers such as the Apple II and Tandy TRS-80 in the late 1970s marked the beginning of the growth of computers in schools. In the 1980s, the curriculum of many schools included teaching *Computer Literacy* as well as some *Computer Science*. Computer use in subject areas followed with the use of databases, spreadsheets, and word processing. Perhaps the biggest innovation though was word processing, which was quickly adopted in many subject areas. Since then, the advent of the Internet, World Wide Web, Wi-Fi, Bluetooth, mobile computers, iPads, mobile phones, and social media has changed the face of educational

computing out of recognition and led to the ways we use computers in education today.

To confuse the issue, there has always been some debate about a title for this area: Computer Science, Computing, Information Technology (IT), and Information and Communication Technologies (ICT) are all titles used by people in different countries. Information Technology today is approached in education in two different ways: teaching about computing in some shape or form (Computer Science) or making use of computers in different subject areas.

This encyclopedia covers all aspects of the use of computers and information technology in every part and form of education. It covers aspects of teaching about computing and use of IT in many different subject areas. It covers computing in early childhood education, computers in primary schools, computers in secondary schools, computer-related professional training and professional development, computers in universities, and computers in training colleges. All chapters have been peer-reviewed by at least two reviewers.

The topics covered include IT and lifelong learning, assistive technologies for special education and people with disabilities, history of educational computing, IT education resources, educational computer games, mobile technologies, designing new educational products, innovation and adoption, computer science, information systems, classroom computing, using the computer as a teaching aid, teachers and IT, computing education research, online learning, global policies and issues, social networking, digital literacy, educational assessment using IT, educational management, IT issues in developed and developing countries, and sociocultural issues with this technology.

Many teachers and academics have worked on writing chapters, and the encyclopedia has been assembled by a team of Section Editors. The encyclopedia has contributions from authors from universities, schools, government departments, and institutions in the following 46 countries: Australia, Austria, Bahrain, Belgium, Canada, China, Colombia, Croatia, Cyprus, Denmark, Estonia, Finland, France, Germany, Greece, Hong Kong, India, Ireland, Israel, Italy, Japan, Kazakhstan, Kuwait, Lithuania, Macau, Malaysia, New Zealand, Nigeria, Norway, Oman, Poland, Portugal, Russia, Saudi Arabia, Serbia, Singapore, South Africa, Spain, Sweden, Switzerland, the Czech Republic, the Netherlands, the Philippines, the UAE, the UK, and the USA.

A hardworking editorial team has brought this encyclopedia into existence through the selection of and invitation to authors and the review of their work. The team consisted of Sigrid Schubert (University of Siegen, Germany), Eric Sanchez (*University of Fribourg, Switzerland*), Jari Multisilta (*Tampere University of Technology, Finland*), Arthur Tatnall (Victoria University, Australia), Vassilios Argyropoulos (University of Thessaly, Greece), Sam Goundar (Victoria University of Wellington, New Zealand), Don Passey (Lancaster University, UK), Bill Davey (*RMIT University, Australia*), Monique Grandbastien (Université de Lorraine, France), Tony Jones (*University of Melbourne, Australia*), Javier Osorio (*Universidad de Las Palmas de Gran Canaria, Spain*), Faten Abdel-Hameed (University of Bahrain, Bahrain), and Joseph Chao (Bowling Green State University, Ohio, USA).

This encyclopedia aims to offer teachers, scholars, parents, and the general public an indication of the breadth and importance of how Information Technology is used in all forms of education. It illustrates the many ways in which IT is being used in education.

List of Topics

Assistive Technologies for Special Education and People with Disabilities

Section Editor: *Vassilios Argyropoulos*

Assisting People Who Are Deaf or Hard of Hearing Through Technology
Assisting People with Autism Spectrum Disorder Through Technology
Assisting People with Physical Disabilities Through Technology
Assisting People with Vision Impairments Through Technology
Assisting Students with Attention Deficit Disorder Through Technology
Assisting Students with Intellectual Disability Through Technology
Assisting Students with Learning Disabilities Through Technology
Assistive Technology and Inclusion, Philosophical Foundation
Assistive Technology and the Gifted Learner
IT on Teaching and Learning Process of Visually Impaired Students

Classroom Use

Section Editor: *Don Passey*

Blending Learning Provision for Higher Education, Integrating “New Ways” of Teaching and Learning
BYOD in the Classroom, Opportunities, Issues, and Policies
Classroom Use, Blended Learning

Collaborative Learning and Patterns of Practice
Computer-Assisted Instruction, Changes in Educational Practice as a Result of Adoption of ICT
Computer-Assisted Learning
Computer-Based Learning, Computational Thinking, and Constructionist Approaches
Computer-Based Training and School ICT Adoption, A Sociocultural Perspective
Distance Learning
E-Books Among Students, Advancements in Higher Education
Educative Value of Digital Storytelling
Ethics and Learning for Teacher Trainees, Team-Based Simulations in Cases of Bullying in School
Flexible and Distance Learning
ICT-Based Inclusive Education
Makerspaces
Mobile Learning and Ubiquitous Learning
Online Teaching, Emotions, and Emoticons in Computer-Mediated Communication
Teaching with LOGO Philosophy
Technology-Enhanced Learning

Computers in Primary Schools

Section Editor: *Anthony Jones*

Algorithmic Thinking in Primary Schools
Capturing Learning Through Mobile Device Cameras
Design in K-5 Programming Projects, Role of Digital Media Boards in Primary Schools, Use of

Digital Storytelling, Information, and Education

About the Editor

Arthur Tatnall

Victoria University
Melbourne, VIC, Australia

Dr. Arthur Tatnall began his career as a secondary school physics and mathematics teacher before getting into computing in the late 1970s when his school obtained a 16k Apple II computer. In the 1980s he went on to become a *Computer Education and General Curriculum Consultant* and later worked as *Educational Computer Systems Analyst* at the Victorian State Computer Education Centre. He served as *Chief Examiner* for Year 12 Computer Science in Victoria from 1984 to 1991. In 1988 he took up a university position teaching and researching Information Systems at Footscray Institute in Victoria and then moving to Western Institute before the two institutions combined to form Victoria University. He has also been *President of the Computing in Education Group of Victoria*, *Director of the Victorian Information Technology Teachers Association*, and *Board Member of the Australian Council for Computers in Education*.

Arthur has undergraduate degrees in Science, Education, and Computer Science. In his Master of Arts research, he investigated the history of the origin of the discipline of Information Systems (IS) in Australia and how universities then devised IS curricula. In his Ph.D., he used actor-network theory to investigate the adoption of Visual Basic into the curriculum of an Australian university.

Arthur is a Fellow of the Australian Computer Society (ACS) and has served on the ACS Victorian Branch Executive Committee. He has been Editor of the *ACS Victorian Bulletin* and a member

of the ACS ICT Heritage Project. He is active in the International Federation for Information Processing (IFIP) as a member of WG 9.7 (History of Computing), WG 3.4 (Professional and Vocational Education in ICT), and WG 3.7 (IT and Educational Management).

He has authored and coauthored a number of computing textbooks and edited several IFIP Conference books. He was also Editor of the *Encyclopedia of Portal Technology and Applications* and, from 2009 to 2016, Editor in Chief of the *International Journal of Actor-Network Theory and Technological Innovation*. He is currently Editor in Chief of the journal of *Education and Information Technologies* (Springer Nature) and has published widely in journals, books, and book chapters.

Arthur's research interests include technological innovation, history of technology, computers in education, IT in educational management, information systems curriculum, and project management. Much of his research is based on the use of actor-network theory.

Introduction

The effects of technology acceptance and innovation diffusion behaviors on information and communications technology-enabled teaching/learning systems (ITLS) adoption attract increasing attention among primary school teachers (Wu and Liu 2015). In particular, Internet-based e-learning has been considered one of the important ICT tools for knowledge providers and receivers to create an exchange process in cyberspace for knowledge development. The system adoption is generally a multidimensional issue that needs to consider such issues as providers' teaching behaviors (e.g., teaching cognition and ICT use preference), characteristics of ITLS (e.g., material presentation, diversity,

and adaptability), and receiver's learning behavior (e.g., learning cognition and ICT adoption propensity) (Bertacchini et al. 2012).

In particular, the provider's teaching behavior based on his or her cognitive system is one of the major determinants of the ITLS utilization (Mampadi et al. 2011). When ITLS providers attempt to describe how effective their tools will be in assisting teachers to develop their ITLS programs, the characteristics of their cognitive system are important to the system design characteristics. For example, a few teachers may need an online community to ease mutual socialization for knowledge exchange and development, whereas others prefer teaching materials developed using multimedia technologies. Certain teachers in a secondary school are unlikely to participate in an online community because of the various cognitions of ICT applications, which need strategies and policies to deal with this issue (Wang and Lu 2012).

One of the relevant methods to motivate pre-service teachers to utilize ICT-enabled tools in teaching is to narrate the existing offerings in the training courses to ITLS available in schools and the methods of using them. This process signifies that the ITLS use perception of teachers varies and should be retreated to maximize the ITLS use with respect to teaching performance. As such, instructors in the current educational environment are required to assume such diverse roles in education as mentors, lifetime learners, curriculum designers, curriculum implementers, teaching assistants, student motivators, peer counselors, teaching consultants, and learning partners. Liaw et al. (2007) conducted a survey and indicated that the teacher-led feature is one of the major determinants that substantially influence the learners' attitude toward e-learning as an effective learning tool. This result implies that teacher roles considerably influence the learning performance under ITLS.

Considerable effort has been exerted to the research, development, adoption, and evaluation of ITLS. In general, emphasis focused on the learner side to enhance the learning performance without considering the personality style of the instructors with respect to the adoption of the cognition-relevant ITLS. As an initiator or

facilitator of learner e-learning use, the propensity of a teacher in using ITLS is crucial for learner use of e-learning. The e-learning critical success factors can be generally grouped into four facets, namely, instructor, student, ICT, and university support (Selim 2007). In particular, the instructors' use of e-learning environments is actually affected by their opinions and propensity to perceive web-based activities and computer-assisted learning. Therefore, the understanding of teachers' adoption intention of ITLS should be deepened to determine the relationship between their cognitive style and propensity to adopt. Accordingly, this study analyzes the factors that explain teachers' willingness or unwillingness to adopt an e-learning system and determine the role of the instructor cognitive styles.

The features of the cognitive style are mainly thinking styles, problem solving, individual perception, and the role of memory and other cognition shown by typical personal traits (Allinson and Hayes 1996). The intuitive and analytical styles, which are called cognitive style index (CSI), are among the many differentiating cognitive styles. The intuitive style prefers free and less-structured thinking behavior, whereas the analytical style is to think with further logic and structure. For example, "People think that I prefer rapidly browsing learning materials" is an intuitive style. By contrast, "People think I usually analyze learning materials with logics" is analytical.

A specific ITLS has been developing its own characteristics that often involve the technology perception and cognitive behavior of users. Its adoption propensity is strongly related to the technology acceptance behavior (e.g., perceived usefulness and perceived ease of use) and technology use behavior (e.g., perceived compatibility) of instructors. The study in the chapter incorporates the behavior of technology acceptance (Davis 1989) and innovation diffusion (Rogers 2003) to derive the research model. An empirical study is conducted on elementary school teachers to analyze the determinants of the adoption intention of ITLS. The moderation effect of the cognitive style on the adoption attitude of ITLS is also presented.

Literature Review

Behavior of Technology Acceptance

The intention of technology acceptance is linked mainly to perceived usefulness and perceived ease of use (Davis 1989) and has been broadly used to analyze the willingness of innovative technology. This idea argues that individuals believe that using a particular technology or system will improve their performance level. When a system is useful and easy to use, it will produce positive intention conducive to adoption. Teachers often consider ITLS as a beneficial tool because they think it can reduce the cost of teaching materials and of teaching itself, enhance the personal accomplishment of information and professional knowledge, and improve teaching performance. The perceived usefulness is related to the course performance in the analysis of the factors that contribute to a successful e-learning environment. The perceived ease of use refers to the extent of personal needs to use a specific technology or system. This study attempts to evaluate whether these factors are also the determinants related to the adoption willingness of ITLS for teachers in primary schools and whether they are moderated by the cognitive styles. The first and second hypotheses are as follows:

- H1: Perceived usefulness will significantly and positively influence the attitude toward the adoption of ITLS.
- H2: Perceived ease of use will significantly and positively influence the attitude toward the adoption of ITLS.

Innovation Diffusion

Innovation diffusion theory is proposed to explain the attitude toward the behavior of technology use, including cognition, persuasion, decision, implementation, and confirmation (Rogers 2003). The behavior of innovation diffusion is linked to five major factors, namely, (1) comparative advantage, (2) compatibility, (3) complexity, (4) to try, and (5) observability. Comparative advantage and complexity factors are considerably similar to perceived usefulness and perceived ease of use, respectively. Compatibility refers to

the similarity between teachers' behaviors in teaching and their original teaching methods if the use of ITLS is considered. This factor is positively related to behavioral intention and perceived education quality to use ITLS that offers online learning courses. Adopting ITLS to assist in teaching is not simply an issue of using ICT tools or their integration. Such issues as similarity of learning and teaching behavior (e.g., pull strategy) and educational policy set (e.g., push strategy) may also need to be considered.

For example, if teachers want to make the materials available in ITLS, then they probably should prepare based on their preferences for and perception of the required software, hardware, and e-materials. Thus, behavior and concept conflicts may occur, thereby probably decreasing the willingness to use the e-learning system. However, if the ITLS education is a set educational policy wherein a teacher has to adapt to using ITLS, then the relationship between perceived compatibility and adoption attitude may change because compatibility may not be an issue for a teacher to adopt. In this case, theory of technology acceptance behavior may explain the situation that behavior is occasionally not self-controllable.

When ITLS enables teachers or students to attempt only part of it, the uncertainty of potential adopters is reduced. Understanding the willingness to attempt an ITLS is highly important to the adoption attitude of ITLS. The advanced ICT has already developed innovative tools and strategies, such as the game-based learning system for learning educational materials in a playful manner, thereby facilitating the educational process. The experience of human-computer interaction frequently marks the playfulness as a predictor of innovation technology use. The effect of edutainment (education plus entertainment) on the increase in motivation was linked to interest/enjoyment and competence (Bertacchini et al. 2012). The playfulness is likely a predictor of the adoption attitude of ITLS for elementary school teachers.

H3: Perceived compatibility will substantially influence the positive attitude toward the adoption of ITLS.

H4: Trialability will substantially influence the positive attitude toward the adoption of ITLS.

H5: Perceived playfulness will substantially influence the positive attitude toward the adoption of ITLS.

H6: A positive attitude will substantially influence the ICT adoption intention.

Cognitive Behavior

Social cognitive theory that is used in explaining learning processes is central to understanding the personality of the learners and instructors (Bandura 1986). Learning is explained in terms of a model, in which behavior, cognition, and environment combine as interacting determinants of one another. Such process is affected by the students' own thoughts, self-beliefs, and interpretation of learning subjects. However, training is believed to be shaped continuously by factors within the environment and thinking behavior of trainers, particularly the technology use perceived by instructors. In general, the stock knowledge of instructors probably interacts with design manipulations when they adopt technology-based learning materials. Teachers use their prior knowledge as basis to possibly prefer ITLS with media-enriched tools to assist in externalizing their knowledge, such that their students can efficiently obtain, relate, and restructure knowledge elements to develop their own knowledge structure. Accordingly, an instructor may argue that reading additional texts (e.g., ICT-based Wiki) can improve performance better than talking to people often (e.g., ICT-based Google talk) based on his or her cognition or experience. This argument may substantially influence the use propensity of ITLS.

The role of cognitive style varies but generally centers on the impact on learners. Research had limited focus in considering the instructor viewpoint by concentrating on the cognitive characteristics that may be linked to the design and adoption preferences. Thus, instructor perception with respect to the cognitive characteristics on the use of ICT tools will likely be related to learning performance. The basic classification of cognitive style is based on the viewpoint of human perception, which can be divided into intuitive and analytical perceptions (Allinson

and Hayes 1996). The analytical type has characteristics in the method of organizing information and messages, such as concise thinking, logical reasoning, analytical functions, and further attention to detail, structured problem-solving style, and methodical approach. The intuitive type tends to involve imagination, understanding, metaphor, rhythm, attitudes, and emotions. This type often changes over time. Problems are preferably solved without any restriction. Cognitive style may influence the teacher adoption intention of ITLS. Thus, the following six hypotheses are formulated:

- H7: Cognitive style substantially moderates the effect of perceived usefulness on the adoption of ITLS.
- H8: Cognitive style substantially moderates the effect of perceived ease of use on the adoption attitude of ITLS.
- H9: Cognitive style substantially moderates the effect of perceived compatibility on the adoption attitude of ITLS.

- H10: Cognitive style significantly moderates the effect of trialability on the adoption attitude of ITLS.
- H11: Cognitive style significantly moderates the effect of perceived playfulness on the adoption attitude of ITLS.
- H12: Cognitive style significantly moderates the effect of adoption attitude and intention of ITLS.

Method

Model

Technology acceptance and innovation diffusion theories are employed to describe the ITLS adoption behavior. The research model presented in Fig. 1 is developed based on the formulated hypotheses. The moderating role of cognitive styles is also analyzed. The independent variables are perceived usefulness, perceived ease of use, perceived compatibility, trialability, and perceived playfulness. By contrast, the dependent variable is

Adoption of Innovative ICT-Enabled Systems for Analysis- and Intuition-Styled Teachers in Primary Schools, Fig. 1 Research Framework

Adoption of Innovative ICT-Enabled Systems for Analysis- and Intuition-Styled Teachers in Primary Schools,
Table 1 Descriptive statistics

Data items	Category	Subjects (<i>N</i> = 340)			Percentage		
		All	Intuitive	Analytical	All	Intuitive	Analytical

	20 h or above	10	3	7	2.91%	30.00%	70.00%

attitude conducive to the intention of ITLS adoption.

Sample

The research population comprised the primary school teachers in a municipality that agreed to participate in the research. The subjects were encouraged to follow the city government's education policy to develop advanced teaching models in primary schools, particularly the ITLS adoption. The city has 49 primary schools and a total number of 2645 teachers. The number of samples for each school was based on the proportion of school teachers to the total number of teachers. Random sampling was conducted to distribute the questionnaires to the class teachers, subject teachers, and administrators. A total of 420 questionnaires were mailed or delivered personally to the schools that accepted participation. The data collection period was 4 weeks. The basic information of the subjects includes gender, teaching age, educational level, and average number of hours per week they use ITLS in teaching.

A total of 340 valid samples were returned (80.95% valid return rate). Of the 340 respondents,

184 were intuitive style and 156 were analytical. Table 1 shows the descriptive statistics. The majority of the respondents were female teachers (80.59%) and most have been teaching for at least 6 years. For the proportion of basic information of the intuitive and analytical types, teachers generally had teaching experiences “within 6 to 15 years” in both styles. Those who teach using the intuitive style account for 58%, whereas 46% employ the analytical style. For the weekly hours using ICT-enabled systems in teaching, most subjects were in the range of “0 to 5 hours,” 54% and 45.5% of which were of the intuitive and analytical types, respectively.

Measure

A questionnaire was designed as the data collection instrument (see Table 2). First, nine items were developed for two variables in the technology acceptance composite. For example, the item “I think ITLS can improve my teaching efficiency” is used for the variable of usefulness. Second, for the innovation diffusion composite, three items were developed for perceived compatibility and three for trialability. For example, the

Adoption of Innovative ICT-Enabled Systems for Analysis- and Intuition-Styled Teachers in Primary Schools, Table 2 Questionnaire design

Composites	Factors	Items
Perception of technology acceptance	Perceived usefulness (PU): subjects perceive that ITLS is useful for their teaching work	PU1: I think ITLS can improve my teaching efficiency
		PU2: I think ITLS can improve the quality of my teaching
		PU3: I think ITLS can ease my teaching work load
		PU4: Overall, I think ITLS is useful
	Perceived ease of use (PEU): subjects perceive that ITLS for teaching work is easy to use	PEU1: I think ITLS is not difficult to use
		PEU2: I think learning how to use ITLS does not need too much effort
		PEU3: I think learning how to use ITLS does not need much time
		PEU4: Overall, I think ITLS is easy to learn
Perception of innovation diffusion	Perceived compatibility (PCOM): subjects perceive that they do not have to change too much of their existing behavior or skills while using ITLS	PCOM1: I think using ITLS to teach is similar to the existing tools
		PCOM2: I think the way to use ITLS in teaching is similar to the way I use other tools
		PCOM3: Overall, I think using ITLS is consistent with my current teaching behavior
	Triability: subjects perceive that trying ITLS is necessary before using it	TRI1: I think it is better to try ITLS before actually adopting it
		TRI2: I think I am willing to adopt ITLS if I am allowed to try it
		TRI3: Overall, I think ITLS should be triable
	Perceived playfulness (PP): subjects perceive that using ITLS is playful and enjoyable	PP1: I think ITLS is interesting.
		PP2: I am happy when I use ITLS
		PP3: I think using ITLS is playful
		PP4: I think using ITLS is enjoyable
		PP5: I think using ITLS can help me explore new things
		PP6: Overall, I think ITLS can enhance teaching playfulness
Attitude	Attitude (ATT): subjects perceive that using ITLS is a positive idea	ATT1: I think using ITLS is a good idea
		ATT2: I think I have a positive attitude toward the use of ITLS
Intention	Intention (INT): users perceive that they will continue (or intend) to use ITLS	INT1: I will be willing to continue using ITLS
		INT2: I am happy to use ITLS now and in the future
		INT3: Overall, I am (will be) sure to use ITLS in teaching

Do you have any comments or opinions on the ITLS adoption? Additional information on your school regarding the use of ITLS is particularly welcome (e.g., policy and strategy)

item “I think the way to use ITLS in teaching is similar to the way I use other tools” is used for the variable of perceived compatibility. Six items were used for the variable of playfulness. For example, the item “I am happy when I use ITLS” is used for this variable. Lastly, two items for attitude and three items for intention were used.

Each variable was measured based on the five-digit Likert rating scale (from 1 to 5) using bipolar descriptors for each question. An open question was also provided at the end of the questionnaire for subjects if they have additional information to provide (e.g., policy, training programs). The CSI questionnaire was used to differentiate the analytical subjects from the intuitive ones. For example, “When I make a decision, I will think calmly then carry out and

complete all relevant factors” is used for the analytical style. By contrast, “I am better in generating ideas rather than handling data of precise information” is used for the intuitive style.

Results and Discussion

Reliability

Table 3 shows the reliability test results. The Cronbach’s α of the overall model was 0.906. The exploratory factor analysis (EFA) using principle component analysis (PCA) was conducted to measure the concepts because the proposed model contained several factors. The PCA and varimax of the orthogonal rotation to derive the factors were utilized. The explained total variance was 79.46%, which is above 60%. Table 4 lists the

Adoption of Innovative ICT-Enabled Systems for Analysis- and Intuition-Styled Teachers in Primary Schools, Table 3 Research variables of cronbach’s α coefficient

details. Factor loading was between 0.662 and 0.919, which is above 0.5.

The model validity test and significance of path coefficient were conducted. For the validity, the model satisfied three requirements, namely, (1) composite reliability (CR) (Cronbach's α) above 0.7, (2) average variance extracted (AVE) above 0.5, and (3) square root of AVE for a factor higher than the correlation coefficient of the other factors. Table 4 presents the test results. The CR value of PU (0.893) was above 0.7. The AVE of PU ($0.822 * 0.822 = 0.676$) was above 0.5, and its square root (0.822) in Table 5 was higher than the correlation coefficient of other factors. Table 6 presents the results of path significance. The explained variance of the independent variables and the dependent variables were 0.659 and 0.463, respectively, and were considered acceptable. Table 7 presents the test result of the

moderation effect. The discussion and implications are provided as follows.

Discussion

Research findings provide several contributions to research theory and practice. The current study describes the research arguments via a basic and rigorous review of literature. This research considers previous theoretical concepts and findings obtained for TAM, IDT, and cognitive styles. The ITLS characteristics are also considered to derive the potential factors that affect adoption attitude, including perceived usefulness, perceived ease of use, perceived compatibility, trialability, and perceived playfulness. This study confirms that perceived usefulness, perceived ease of use, trialability, and perceived playfulness

substantially affect the ITLS adoption attitude conducive to adoption intention.

First, the perceived usefulness does have a substantial effect on adoption attitude (see Table 6). Education-supported tools or strategies need multiple channels and media-rich presentation to efficiently bring materials and knowledge into situations where teaching/learning occurs. Although ITLS in cyberspace is increasingly changing the way teachers are pursuing education, the analytical- and intuitive-styled teachers in primary schools likely accept ITLS as one of

the important tools to satisfy their teaching needs and wants.

Second, the perceived ease of use for the entire subject is significantly related to the adoption attitude toward adoption intention. However, the moderation test shows that analysis-styled subjects do not support this situation, thereby signifying that these subjects are more unlikely to care whether ITLS is easy to use. On the one hand, the type of analysis style has characteristics in the method of organizing teaching materials, such as concise thinking, logical

PU perceived usefulness, PEU perceived ease of use, PCOM perceived compatibility, TRI trialability, PP perceived playfulness

reasoning, analytical functions, additional attention to detail, structured problem-solving style, and methodical approaches. These teachers tend to be considerably confident in analyzing and organizing teaching materials based on their own perceptions and preferences. However, these observations do not imply that the subjects with this cognition style completely ignore whether ITLS is easy to use. They are likely to be involved in the development of ITLS based on their preferences and may disregard ease of use as an adoption barrier.

On the other hand, intuitive people prefer diverse and less-structured thinking behavior. They tend to be substantially imaginative, empathic, and emotional with respect to the characteristics of the ITLS that they can use (e.g., online talk and animation). This view implies that they prefer teaching with substantial freedom or without excessive involvement in developing or using the ITLS and prefer ICT tools that are easy to use. Therefore, to promote ITLS in teaching, vendors, agents, and consultants should first understand the users' cognitive style. If the intuitive style is substantially dominant, then

additional attention should be focused on designing ICT tools that are easy to use.

Third, perceived compatibility is an insignificant factor for the intuitive and analytical groups. Accordingly, the compatibility of perception of the intuitive and analytical styles to the use of ITLS with the existing teaching behaviors is insignificantly linked to their ITLS adoption attitude. A response from a few subjects and their questionnaire responses showed a major reason. The subjects realized that they have to directly accept ITLS for their teaching endeavor because of the school policy. In general, the research subjects of the analytical and intuitive styles are not ICT professionals. ICT is merely a teaching aid. To date, the general use of the ICT experience or personal habits in teaching endeavors may be different for individuals. They have to change their existing teaching concepts and behaviors to adapt to the needs. Therefore, compatibility perception may be quite different with respect to its influence on the adoption attitude of ITLS.

Fourth, the subjects are significantly willing to attempt a teaching tool before they adopt it. Thus,

trialability is important to the enhancement of the adoption willingness of ITLS. In general, most elementary school teachers have non-IT-related professional backgrounds. They often have to train frequently and continuously use new technologies to ensure they know how to considerably operate these technologies.

Fifth, perceived playfulness shows a significant effect on the adoption attitude of ITLS. The ITLS or educational strategies need innovative technologies to satisfy the teaching/learning needs of the “e-generation.” Accordingly, responding to the needs may require varied media-rich materials to efficiently present educational information and knowledge in general and enjoyment-based learning process to motivate learning attitude in particular. Edutainment that combines education theory and entertainment may be one of the solutions that researchers, vendors, consultants, and government agencies consider for the development of ITLS. Lastly, adoption attitude is substantially related to adoption intention, which is a result that is also true for the analytical and intuitive subjects.

Moreover, the overall results imply that emphasis should be placed particularly on usefulness, trialability, and playfulness to attract the attention of school teachers. Toward this aim, primary teachers can explain that ITLS assists in presenting teaching materials in a media-rich manner, ease the communication with learners, develop an immersive environment, and enhance learning enjoyment, among others. In addition, the intuitive subjects prefer the easy-to-use ITLS, whereas the analytical subjects are unlikely to be concerned with the ease of use but do need involvement in the development of ITLS tools. These findings will be useful for ITLS providers and consultants to analyze the requirements of their school teachers, particularly the consideration for cognition characteristics. Moreover, the result discloses that the analytical and intuitive subjects are not excessively concerned with the issue of compatibility with respect to the effect of adoption attitude. Under the established education policy and strategy as well as the removal of the adoption barrier, this finding can serve as an aid for researchers, vendors, consultants, and

government agencies to persuade primary school teachers to adopt ITLS.

Conclusion

Primary school teachers are concerned with technology acceptance and innovation diffusion behaviors as the major determinants of ITLS adoption. Communication between instructors and learners via ITLS is a requirement in knowledge development because connections are established through externalization (instructor side) and internalization (learner side), thereby involving such variables as behavior, cognition, and technology-mediated environment. The cognitive styles were utilized to classify the sampled subjects and the moderation effect was tested to provide additional information on the adoption willingness of ITLS. Additional focus on the result limitations and implications should be provided with respect to the school level and cognition differentiation base.

A transition gap exists in the literature. Such issues as virtual instruction for the knowledge-provider side (e.g., online structural materials based on instructor cognition), ITLS for knowledge development platforms (game-based teaching/learning systems), and virtual self-learning process for the knowledge-receiver side (e.g., personalized materials based on learner cognition) should be considered in future research. Furthermore, the current research conducted a quantitative study without in-depth investigation on cognitive issues from a qualitative perspective. Therefore, a research direction may be a case or multi-case study to report additional findings on ITLS adoption and performance and offer suggestions thereafter for the ITLS vendors and agencies.

Introduction

In developing countries, literacy is crucial key for socioeconomic growth, and for achieving sustainable development goals, education platforms enabling remote or classroom didactic education must impact millions of students and teachers irrespective of geographic or infrastructure barriers. With the use of ICT in didactic laboratories, over the last three decades, several online educational tools have promoted enhanced learning and teaching experiences across communities of users (Youssef and Dahmani 2008; White 2008). Addressing the challenges of inquiry-based science learning, some of these ICT tools focus on augmenting skill training and supporting lecture courses with easily accessible online tools that can deliver laboratory skills through computer-based interfaces (Chu 1999; Harward et al. 2008; Diwakar et al. 2011; Heradio 2016). Virtual laboratories have also been presented as complementary education tools and as ICT platforms for sustainable education (Bocconi et al. 2013; Srivastava et al. 2013; Radhamani et al. 2016; Kumar et al. 2017). Besides, in biology, virtualization of wet-lab techniques have improved individualized education and increased the scope for flexible tools for students in remote areas in developing nations (Nair et al. 2012).

In India, government programs (MHRD 2016) for exploring e-learning were initiated for facilitating education for the masses and towards connecting teachers and students in formats including recorded lectures, smart boards, audio and visual tools (Bijlani et al. 2012) and education tools, and mobile applications. Through such projects, there have been a significant number of online laboratories reported for high school education (Nedungadi et al. 2015) and University-level education (Raman et al. 2011; Achuthan et al. 2011; Srivastava et al. 2013; Diwakar et al. 2015; Radhamani et al. 2015). With an entire nation in focus, Virtual Labs project, launched by Ministry of Human Resources Development (MHRD), under National Mission on Education through ICT, Government of India, was set up jointly by top-tier engineering institutes with the focus of developing and providing advanced training environment aimed at solving issues

faced classroom laboratory education. This team had designed, developed, and deployed experiments in biological sciences, physical sciences, chemical sciences, mechanical engineering, computer science engineering, and cybersecurity systems.

Virtual laboratories have been developed as multiple content and media models including animations (McClean et al. 2005; Radhamani et al. 2014), mathematical simulations (Parasuram et al. 2011; Murray 2002; Diwakar et al. 2014), remotely controlled hardware models (Ma and Nickerson 2006; Kumar et al. 2014), and analogue equivalents of realistic dynamics (Sridharan et al. 2016). Development (McClean et al. 2005; Diwakar et al. 2014) and deployment of virtual laboratories (Diwakar et al. 2014, 2016a) relate multiple elements connecting didactic education (Sajid et al. 2013; Herga et al. 2016), educators (Donovan et al. 1999; Houts et al. 2006; Diwakar et al. 2011; Svoboda and Passmore 2013), content (Eggen and Kauchak 1988; Sheorey and Gupta 2011), and access modalities (Youssef and Dahmani 2008; Noor-Ul-Amin 2013; Kumar et al. 2015; Alkhaldi et al. 2016).

Virtual Laboratories as an E-Learning Platform in India

Since 2009, we were involved in the development and deployment of virtual laboratories (www.vlab.amrita.edu) to complement classroom courses and accessible freely over the internet. As a consortium, India's Virtual Labs project had developed over 1000+ experiments for undergraduate and postgraduate students and as tools for teachers (Diwakar et al. 2015, 2016b). The target of development of such laboratories was handling insufficiency in numbers of trained experts for educating millions of graduating STEM students, unavailability of expensive hardware or experimental setups, and ability to enable extended access unrestricted by geographical or time constraints (Huang 2003; Diwakar et al. 2012).

The development of content was based on syllabi in most universities and modified to

suit teacher-independent education in and outside classrooms (Diwakar et al. 2010; Raman et al. 2011, 2014). India's virtual labs were also developed to cater towards resource or content unavailability and to help teachers and institutions who faced regression in student interests in science and technology experimentation (Diwakar et al. 2011; Achuthan et al. 2011).

Virtual labs were deployed in three modalities. Animation-style labs involved non-interactive or interactive graphical emulations capturing an experiment in terms of manipulating materials and equipment, or the temporal procedure including critical to-dos and do-nots (Radhamani et al. 2014). Simulation-based virtual labs employed mathematical approximations to generate realistic yet computationally feasible emulations of real-world conditions. Simpler mathematical models like logistic growth, predator-prey equation, spiking neuron models help resolve complex biological properties with equivalents for pedagogical benefits (Parasuram et al. 2011; Diwakar et al. 2016a). Remotely controlled experiments enable access to remote equipment and serve as an interface to perform real experimentation or with analogue equivalents serve to virtualize real experiment practice and data collection. Such experiments serve to help reduce accessibility or lab usage issues (Freeman et al. 2012; Kumar et al. 2014, 2015; Vijayan et al. 2017). The national platform consortia had established more than 1000 online experiments and are freely available via <http://vlab.co.in>.

Comparative Analysis of Virtual Labs

The cost-benefit analysis was estimated by comparing direct and indirect costs of laboratory skill training with and without virtual laboratories (Achuthan and Murali 2015). With an increase in student performance higher than 80% (Achuthan et al. 2014; Achuthan and Murali 2015) in over 40% students using physical lab to around 70% in students using both platforms, evaluations related the efficacy of virtual labs in classroom education.

The study related learning outcomes, time for learning, setup cost, safety, and facility requirements and assumed 800 square feet classroom for laboratory education and appraised 48% savings in tangible costs with virtual laboratories instead of physical laboratories suggesting additional training hours could be cost-effective, if performed on virtual platforms rather than physical laboratories. A cost order of Indian rupees 3 million was shown as a comparison for physical laboratories and virtual laboratories performing chemistry experiments being used in resource-restrained environments. The study also suggests selection of experiments could be based on cost, facilities, safety, time, and learning modalities relating physical laboratory, virtual laboratory, expensive physical laboratory, or remotely controlled laboratory choices. Physical labs and expensive physical labs (with equipment or resources being more uncommon) were not feasible for situations involving large number of student learners. Our study suggested low maintenance yet scalable labs were significantly cost-effective.

Evaluating Virtual Laboratory Usage

Learning outcomes have been shown to be improved by content consumption in addition to quality of learning material (Collis and Moonen 2001; Anderson 2007). Analyzing teacher-student interactions (Chu 1999; Sousa et al. 2010) and the usability of ICT tools (Bocconi et al. 2007; Vilaseca-Requena et al. 2007; Nair et al. 2012; Fathima 2013) such as virtual laboratories have been done across several case studies in multiple modalities (Guma et al. 2013; Achuthan et al. 2014; Kumar et al. 2015).

Another study had taken animations and simulations-based virtual laboratory and had evaluated the relative advantage, ease of use, and perceived usefulness among students and teachers (Diwakar et al. 2014). In technology acceptance model (TAM), usefulness is a criterion representing acceptance by users. The increase in usage also related to representation of general curriculum (Diwakar et al. 2011).

Usage/design scalability, deliverability efficiency, network connectivity issues, security issues in developing and implementation online laboratories in biotechnology courses were perceived critical in initial development and deployment of curriculum-specific virtual laboratories in India.

A previous paper (Diwakar et al. 2016a) had focused on the development, deployment, and implementation of 20 web-based virtual laboratories involving more than 170+ online experiments in Biotechnology and Biomedical engineering disciplines on students across villages in India. Pedagogical studies on didactic undergraduate and post-graduate classrooms involving remote labs reported the usage trend beyond scheduled classroom hours and the effective use of remote labs as a learning material towards laboratory examinations. Perceived relative advantage for remote lab users indicated the use of online labs as a next-gen interactive textbook for teachers and students in practical skill education. A small percentage of users reported learning issues in connection with poor internet connectivity and device failures. This implied several practical issues need to be resolved before deploying virtual and remote labs as a massive online course. A study on neurophysiology virtual labs suggested employing ICT-based skill training complemented as a cost-effective methodology for enhancing neuroscience education especially, in financially and geographically challenged nations like India (Diwakar et al. 2014). Remote labs have also been assessed as a self-learning material for robotic education (Vijayan et al. 2017). Using metacognition, analytical thinking, and transfer of knowledge, virtual laboratories in chemistry indicated students showed augmented reflective learning and information retention when virtual labs were introduced before physical laboratory training (Achuthan et al. 2017). Alternate concepts of chemistry students on molecular symmetry were evaluated after students used virtual laboratories (Achuthan et al. 2018). The virtual lab-based study had suggested identifying concept-based learning as relevant for perceiving alternate concepts among learners.

Technology Adoption: Criteria and Design Restraints

Several diffusion-of-innovations theories and models have emerged in order to study community members' acceptance and assimilation of these innovations (Venkatesh et al. 2003). Understanding technology adoption and diffusion of innovation play a vital role in outreach extent of new technologies by determining acceptance factors and new adopters' behaviors. A general framework on the social impact of technologies on people can also provide insight into the characteristics of technology that may influence specific groups to adopt them (Chuttur 2009). Research on innovative technologies in education has recommended several factors including technology design, instructional methods, and students' characteristics contribute to the effectiveness of technologies (Raman et al. 2014).

Laboratory exercises in STEM (Science, Technology, Engineering, and Mathematics) areas often require effective skill acquisition and hands-on roles for sustained skill training. In such scenarios, a virtual laboratory has to be modelled to meet the user requirements, namely: data collection, data measurement, data analysis, equipment handling, discarding biological hazards, use of explosive chemicals, among others. With design of effective learning tools, online laboratories have improved better understanding, facilitated problem-solving skills, and facilitated observation quality in a class of students. This has allowed overcoming challenging aspects of traditional classroom education in geographically and economically backward institutes such as time-constraints and scarcity of laboratory resources for delivering a high-quality education (Radhamani et al. 2016; Diwakar et al. 2016a; Nutakki et al. 2017). Although technology platforms need to account usage time to assess behavioral patterns, there is no significant indication in the literature regarding time users need to spend with an innovation prior to making the decision to adopt it into regular practice.

Dissemination of Virtual Laboratories: An India-Based Model Approach

In 2011, a nodal center program was conceptualized for dissemination and involved induction of science and engineering education institutes partnering to become early adopters of innovation in their regional areas. The induction of nodal centers was based on an institute's interest to join the program and were ensured support and assessment tools. Classroom integration of content and virtual lab methods were introduced to teachers who were part of the nodal center. Workshop-based hands-on training to faculty members was a part of the nodal center program. Assessment tools involved multiple choice questionnaires and descriptive questions for institutions and teachers to assess student's perception of technical concepts and to report the user experience. An annual conference allowed attendees to have hands-on training and opportunities to interact and provide feedback. Nodal centers and its associated students and teachers have been supported periodically with training sessions online and/or onsite. Today, we see a 25-fold increase in nodal centers compared to 2011 and more than a million active usages.

An analysis of technology adoption using Roger's model (Lee et al. 2011) suggests five types of adopters: Innovators (2.5%) were developer universities and institutes of national importance and ranked research intensive private universities. Early adopters (13.5%) included top colleges, large public or state universities and private universities (who became the nodal centers) tending to be opinion leaders in the social system and influenced the decisions of others. Combining the innovators and early adopters gets 16% and these two groups typically gives all the information of the product system. Early majority (34%) included colleges affiliated to universities that were rarely leaders but adopted new ideas and implemented them. Late majority (34%) were institutions that tried innovation after many had already incorporated and tested them. Both early majority and late majority comprise 68% of the adopter categories and their characteristics tend to be similar. Laggards (16%) were a few institutions

that were most difficult to be persuaded to adopt innovations and were insignificant diffusers of innovation.

User's Role in Autonomous Learning via Virtual Laboratories

Through feedback-based analysis, studies show students who performed virtual laboratories were able to learn concepts of experiments in an instructor-independent manner implying augmented self-organization abilities among students, facilitating reduced student-teacher interaction within crowded classrooms. Biology and biotechnology students preferred virtual laboratories as a pre-lab material to acquaint the basics of each experiment before practicing it in a wet lab. Workshop participants from India's rural and geographically remote non-city regions perceived remote labs as a distant education tool for equipment training and as a platform that allowed repeated usage of devices beyond scheduled classroom hours. Some issues related to poor usability of the remote labs were correlated to technical issues and inconsistent network connectivity. Deployments suggested low-cost and feasible FOSS-based implementation augmented student-teacher interaction and usage adaptability with remote labs.

Usage data from direct feedback suggested 82% users were able to use and adapted to self-organized learning through an ICT environment. Towards developing a more substantiated assessment of virtual labs, online feedback from 300,000 users received till January 31, 2018, were processed. Around 49,800 valid feedback inputs were evaluated for testing the virtual lab adaptability and its usage in the curriculum of university education in science and engineering disciplines all over the world. Fifty-eight percentage (28,884) of users rated virtual laboratories as an excellent tool for ease of use, 20% (9960) of users rated it as very good, and 18% (8964) indicated as it as a good platform for laboratory education.

A small percentage of users found it difficult to work with the virtual lab experiment and thus they

rated the technical support of virtual laboratories as average (2%, 996) or poor (2%, 996). This was related to students who faced connectivity or computer-usage issues while working with virtual lab experiments. Statistics showed that 62% (30,876) users supported the use of virtual laboratories as a complement to classroom education, 15% (7470) rated as very good, and 10% (4980) each suggested it as a good or an average tool after performing the virtual laboratories experiments. A small percentage of users (3%, 1494) rated it as a poor online material.

Among university-level teachers who participated in the remote lab workshop, 84% suggested that advanced technologies like remote controlling of lab equipment were helpful in their classroom scenario, whereas 16% did not favor use of such tools in blended learning. A participating college teacher commented: "Although the remote lab did not feel as real as the actual lab, remote labs allow students (to) practice the experiment many times and compare the results in order to have a better idea. This reduces our efforts in teaching the experimental concepts in the classroom so many times."

Virtual Labs and Extensions

While animation and simulation-based virtual laboratories were apt for most classroom-related practical courses, complementing remote student education may need specific design and deployment considerations while translating usage across regions and disciplines. Assessing trends of usage seem crucial to make such tools reliable for student learners in daily education. Biology students expect media-rich translations for higher usage and engineering students rely on content and interaction-rich environments. Remote laboratories with setup handling were not the most favorite among students in rural India. Such outcomes may also need more extensive testing. Effective learning strategies are yet to be perceived while major focusses have been on assessment of usage and use-related scoring. Our deployment and usage-based studies suggests nodal center outreach as early adopters was

effective for curriculum-related laboratory skill enhancement. Although continuous development and constant upgrades and new content are needed, statistics indicates steady increase of new users on virtual laboratory platform suggesting a general acceptance by teachers and students as a complementing laboratory skill-training resource.

Acknowledgments The work in this chapter derives ideas and inspiration from the Chancellor of Amrita Vishwa Vidyapeetham, Sri Mata Amritanandamayi Devi. The work was funded by Virtual Labs Phase I, II and III of Ministry of Human Resource Development, Government of India and by Embracing The World Research-for-a-cause initiative.

Introduction

Connectivism is a learning theory which has been gaining ground in higher education in recent years. Its currency could be attributed to the rapid development of emerging technologies, which has impacted on the ways in which knowledge is produced and accessed (Downes 2005; Siemens 2004, 2009). As a theory, connectivism is often referred to as *networked learning* involving more than just the technology used to achieve the end result (Darrow 2009). Connectivism assumes that “knowledge is distributed across a network of connections and knowledge nodes” (Downes 2012). Social media can be used to connect to some of these nodes of knowledge

and facilitate further knowledge development on the premise of collaboration and sharing.

Although much has been written about connectivism since it was first coined by Siemens (2004) and Downes (2005) as a new learning theory, not much has been written about the affordances of connectivist tools for educational purposes. One of the problems with introducing connectivist tools into higher education is that academics are often not au fait with their use for educational purposes (Johnson et al. 2014; Seaman and Tinti-Kane 2013). In order to use these tools for educative purposes, higher educators would have to be inducted into their use in teaching and learning (Johnson et al. 2014; Stevenson and Hedberg 2011). To disseminate knowledge about connectivist tools, it is necessary to provide professional development for academics on the use of these tools for pedagogical purposes (Ng'ambi et al. 2013) and in reporting on how the academics experience these endeavors. As Anderson and Garrison (in press) note, the support needed to help teachers access and organize instructional content through the www is very important. "Teaching in a global, information-rich environment is a very different experience from teaching in a closed classroom." Unfortunately, academics remain uncertain and even fearful about the use of connectivist tools such as social media in their pedagogical practice as doing so requires them to abandon many conventional teaching and learning practices (Adria and Rose 2004). There is thus a need to investigate the use of connectivist tools such as Google Drive, WhatsApp, and Skype from the learner's perspective (Rambe and Nel 2014; Stevenson and Hedberg 2011).

This entry reports on the experiences of a group of university lecturers who were enrolled in an interinstitutional Postgraduate Diploma in Higher Education Teaching and Learning. The group of participants in the study was involved in an assessment task which entailed investigating a specific learning theory and developing a collaborative assignment on this theory. Our particular group was allocated "connectivism" as their learning theory. During the process of completing the task, the group researched on connectivism as

a learning theory and used connectivist tools such as Google Docs, Google Slides, Google Forms, WhatsApp, and Skype to investigate and develop their assignment. It was decided during the course of completing this assignment that group members were interested in disseminating their experiences of doing this task and their views on the pros and cons of connectivist tools. Toward this end, auto-ethnographic data were collected through a Google Forms where the participants shared their experiences and perceptions of connectivist tools and their various affordances.

This entry provides a brief overview of connectivism, connectivist tools, and the affordances of the specific tools which are considered in this entry. This is followed by a description of the methodology used, after which the findings are presented and discussed, as well as their implications for the higher education context.

Connectivism

In proposing connectivism as a learning theory for the digital age, Siemens (2004) characterizes it as a successor to behaviorism, cognitivism, and constructivism (Bell 2011). These antecedents to connectivism had their limitations in the form in which they viewed intrapersonal learning; their failure to address the learning that is located within technology and organizations; and their lack of contribution to the value judgments that needs to be made in knowledge-rich environments (Siemens 2004). Connectivism offers the platforms to shift teaching and learning practices in the twenty-first century.

In connectivism, learning takes place when learners make connections between ideas located throughout their personal learning networks, which are composed of numerous information resources and technologies (Dunaway 2011). One of the underlying principles of connectivism is that the capacity to know is more critical than what is currently known (Siemens 2008; Wang et al. 2014). Connectivism is driven by the understanding that decisions are based on rapidly altering foundations, where new information is continually being acquired and shared (Siemens

2004). From an epistemological point of view, learning in connectivism takes place by connecting to different nodes of knowledge across cyberspace, objectively analyzing and reviewing the gained knowledge. This process is aided through critical discussions and social interactions using social media. Technology used was blended in the form of cloud, social network, online voice integration, in this entry enhanced real time communication among participants and provided a platform for social creation of knowledge (Callaghan and Bower 2009; Rowe et al. 2013).

Connectivist Tools

Connectivist tools are used for learners to interact by creating and sharing knowledge, and are based on emerging or Web 2.0 technologies, made possible through the social web (del Moral et al. 2013). Shared working spaces for collaborative projects such as Google Drive and its various tools, such as Google Slides, Chat, Docs, Forms, etc., and WhatsApp and Skype for communication are some examples of connectivist tools which can be used for teaching and learning purposes. Through these connectivist tools, the learner is able to become an active and visible node in the learning network, contributing resources and ideas and participating in the collaborative creative process (Pettenati and Cigognini 2007). A clear implication of using connectivist tools and other social media is that the learners should be “active co-producers” of knowledge rather than “passive consumers” of content and subsequently that learning should be participatory (Selwyn 2012). Establishing how higher educators and learners perceive connectivist tools and how they understand the affordances of these tools is important for enhancing their use for educational purposes (Rambe and Nel 2014).

Affordances and Connectivist Tools

In recent years, the term “affordance” has increasingly appeared in educational literature, especially related to the use of online technologies in

education (Bower 2008; Conole and Dyke 2004; Day and Lloyd 2007; Gee 2014). In order to understand how attributes of online technologies interact with other elements of a learning context, including learners, teachers or educational practitioner, and the physical environment, it is necessary to understand affordance theories (Day and Lloyd 2007).

“‘Affordance’ refers to the perceived and actual properties of a thing, primarily those functional properties that determine just how the thing could possibly be used” (Salomon 1993 cited in Conole and Dyke 2004). When considering how to match learning tasks with technologies, it is useful to have a knowledge of the affordances of the technologies (Bower 2008). The term “affordance” was coined by the ecological psychologist Gibson (1977) and adapted by Norman (1988) for the design of everyday objects who distinguished between “real” and “perceived” affordances (Day and Lloyd 2007). In the original description that Gibson provides, an “affordance” is present as long as the organism is physically able to undertake the required action and as long as the possibility of executing that action is present (Bower 2008). In other words, affordances relate to the *action possibilities* (Gee 2014) that exist for connectivist tools. Affordances are therefore relational in that they concern the opportunities a connectivist tool offers and provides for action and how these qualities are taken up by the person using it.

Real affordances are not nearly as important as perceived affordances which signal to the user which actions can be performed and how they may be accomplished (Bower 2008). Gibson (1979) and James Paul Gee (2014) take this important point on perception of affordances forward by observing that unless an individual can *perceive* the possibilities connectivist tools provide, these tools are unlikely to be used effectively. In order to take advantage of the affordances or possibilities of a connectivist tool, “*effectivities*” are necessary (Gee 2014; Gibson 1979). Effectivities are “the set of capacities for action that the individual has for transforming affordances into action” (Gee 2014). These effectivities are thus necessary for academics and

students using connectivist tools in educational contexts so that they can be used in ways which take the learning forward. This is why it is important to engage with academics and students around the use of these tools for pedagogical purposes. Thus, the concepts “affordances” and “effectivities” are relational in that they are dependent on both connectivist tool and the ability and perception of the academic or student to use the tool for educational purposes.

This study sought to investigate was how the affordances of connectivist tools for teaching and learning were perceived by a group of learners who were educators in institutions of tertiary education. Specifically, the tools under examination were Google Drive, WhatsApp, and Skype.

During the course of engaging with the task, the group members became interested in the efficacy of utilizing connectivist tools to prepare and complete their assignment, particularly since they were located in geographically disparate spaces. The formal work of the assignment was conducted on Google Slides presentation, with collaborative writing and posting of graphics from group members and feedback to each other in the comments and chat boxes on the side. A Google folder for readings was uploaded for any useful texts that group members and the facilitator were able to source. In order to gather data for the study, a Google Forms questionnaire was sent to all group members, including the facilitator. At the same time, through the narrative, the participants were able to reflect on the experience. Auto-ethnography is defined as a qualitative research method that uses data about self and its context to gain an understanding of the connectivity between self and others within the same context (Ngunjiriet al. 2010). The auto-ethnographic researcher strives to examine his or her experiences in relation to others who have encountered similar circumstances as a way to identify a pattern, theory, or thread inherent to the group (Raab 2013).

The responses from the participants resulted in the close scrutiny of the affordances of the connectivist tools used in the assessment task, in terms of what the possibilities that various tools were able to provide or not provide for the

purposes of completing the assessment task given to the group.

Collaboration

The use of social media was perceived as enabling group collaboration and the ability to complete tasks assigned to group members, particularly since members were geographically separated. Rambe and Nel (2014) also noted that educators in the South African context reported on the opportunities that social media present for collaborative purposes. One of the participants commented, “from my experience, the use of these social media (i.e., WhatsApp, Google Docs) was an important aspect for the successful completion of the assignments (1&3).”

Familiarity with Connectivist Tools

One of the participants, who came from fields such as Information Sciences, indicated his familiarity with the use of social media: “Exposure and deep knowledge of IT made it easy for me to use social media.” Another participant found Google applications to be well designed from a technical viewpoint and was able to express this eloquently:

Google drive, presentation and docs are very user friendly. Google has been great by not attempting to redesign the interface, but rather use an interface that is familiar to most users. This makes all google applications easy to figure out and follow. The use of a great, simple intuitive interface is in my mind the key to their success and why I like using those platforms.

Participants found the use of tools for educational purposes to be more conducive when they were familiar with them, “WhatsApp was easy as I am familiar with it.” Conversely, when participants had not used the tool before or were unfamiliar with it, they found that their participation in the group activities was impeded, “Google presentations was not as easy to use as PowerPoint (which I am used to) as it was a bit slow and froze at times which was frustrating and it was unfamiliar.”

The Personal and Professional Boundaries with WhatsApp

The fact that participants found WhatsApp an easy connectivist tool to use did not mean that there were no problems with its application for educational purposes. Because participants were used to using this tool for social and personal purposes, participants found it more difficult to confine the discussion to educational matters. Rambe & Bere (2013) and Madge et al. (2009) have also noted the difficulties in traversing personal and professional boundaries in relation to mobile learning, similarly with Facebook for learning. One participant observed:

When it comes to WhatsApp use, it was the easiest of the tools as most people who own smartphones would utilise it on a day to day basis. That being said, the fact that it was easy to use, does not mean that it was not challenging to control what was being discussed.

Google Docs and Presentations, on the other hand, were not familiar to all participants, and they related these tools more with the tasks at hand than with socializing with their peers:

Google Docs and Presentations were new media platforms for me. I truly enjoyed learning about their potential use. Between the two I would say that Google Presentation was the most challenging as there are many options one could make use of.

Skype was also a familiar tool to most participants who had used it to communicate with others across geographical distances. Skype is a familiar social media platform for me, although I rarely use it.

Uneven Communication Through Social Media

Participant 1 and Participant 2 were great at communicating and interacting and drove our group assignments – I am grateful for this. Due to the distance, it was not easy to interact with Participant 3.

As can be seen in the above quote, some participants took more responsibility than others and made far more use of the connectivist tools to work on the

task, 'I tend to take the reins of group work when things are not going according to the original plan.'

Two group members took a leading position when working on the assignment - as one of them noted:

We had frank conversations about the course and the assignments. I always felt we had a good synergy. The other two members were a bit more distant in terms of the way we engaged but towards the end of Assignment 3 we had managed to establish a good rapport

Affordances of Tools as Perceived by Participants

The affordances of the different connectivist tools which were used regarding matching the teaching and learning tasks which the group members had to complete, and the processes involved in doing them, were commented on by the participants. They examined the attributes of the connectivist tools and what they made possible in terms of the group communication and abilities to collaborate on the course assignments.

Social Media

Group members were working academics who had little time to meet face-to-face with their work and family responsibilities, and social media provided a flexible platform for communication under these circumstances.

We only met face-to-face a few times, most communication was done via WhatsApp and the Google drive. There were times I realise I could have been better at communicating, this was due to pressures relating to work, home responsibilities and the course and having to prioritise each of these at different times.

WhatsApp

WhatsApp was seen as providing group members with immediate notification (Church and De Oliveira 2013) and coordination of upcoming deadlines: "With WhatsApp, the messages are instant although there is no face to face." Another member commented on the fact that WhatsApp was not used

to engage with the task but to arrange meetings and alert people to what was happening currently and what was being planned in the group:

WhatsApp was mainly used as an organizational tool with little to no interaction about the topic or task at hand. This I mainly ascribe to the laborious nature of entering text on a cellphone. But WhatsApp did provide social interaction promoting motivation and group coherence.

Google Drive

The Google Drive was used for working collaboratively on the task at hand both synchronously and asynchronously. The Google platform provided a much better platform for task-oriented interaction. The interaction taking place while all simultaneously working on the same project was amazing as interaction and comments in real time. However, our interaction was also asynchronous via comments and replies. Similar affordances of Google Drive were found by Rowe et al. (2013). Participants were highly enthusiastic about the affordances of Google Drive for the educational task:

The best platform for interaction was Google presentation with the built-in chat facility for task orientated learner-learner interaction. The reason it is so effective is because it has the chat function which allowed real-time chats, input, I think the true reason it was the most effective tool is because we were actually working on the task, thereby the conversations were guided to be task orientated and generally didn't shift into the social paradigm like WhatsApp for example. In addition, Google presentation allows for the asynchronous communication in the form of comments and input to which one can respond to at any time removing the time constraints. Furthermore, the comments are left directly on the task, making it easy to follow the meaning. Often in emails it becomes difficult to figure out exactly to what the comment pertains in particular if its attempting to address issues of formatting.

Google Drive was seen as the most useful tool for a number of different aspects of the task. In the participants' descriptions below, the accessibility, view-ability, read-ability, write-ability, share-ability, collaboration, move-ability, large size-ability, upload-ability, dialogue-ability, accessibility, synchronicity, revision-ability, browse-ability,

search-ability, build-ability, communicability, and interaction-ability are mapped out:

We could access the material from any location as well as share information among the rest of the peers.

Google drive allowed for uploading of large file sizes and instant feedback that involved commenting electronically. There was online collaboration of work activities among the group members involved in the project.

I think Google Drive was great to build and develop learner-content interaction. We could access the material from any location as well as share information among the rest of the peers

Google Drive was great to build and develop learner-content interaction. We could access the material from any location as well as share information among the rest of the peers.

For some participants, while Google Drive had many affordances, it was not sufficient altogether to accomplish what needed to be done. Some participants noted that they needed to do individual work to prepare for the collaborative work in groups:

group engagement with the content occurred in the creation phase on Google presentation, but it was often not in depth. The more in depth discussions occurred face-to-face.

Some form of content interaction occurred on Google presentation, but I think the majority of interaction with the content in my case occurred by reading and analysing pdf and word documents myself, in other words individual content engagement.

Google drive was where we could access useful and relevant content. I did however find a lot of articles and papers through my own searches online.

Skype

Skype was the choice of tool to have more extended conversations between group members who were distantly located geographically: "I used Skype for conferencing with group members at a distant away from the physical venue." However, Skype was not perceived by participants as being reliable in its communicative affordances:

Skype is a platform I find least useful. There are always problems with connection particular when

more than two people want to engage in the conversation. Often it is difficult to hear and there is always someone that is not sure on how to connect. Therefore, I rate Skype as being a difficult platform and avoid using it as a tool unless there is no other option.

Participants perceived connectivist tools used in this study, viz., WhatsApp, Google Drive, and Skype, to have various media, spatial, temporal, navigational, and accessible affordances for the task they were required to complete. These tools provided different affordances needed to complete the task – WhatsApp for alerting members to what was happening, Google Drive for collaborative work on the task, and Skype for verbal conversation and planning regarding the task.

Conclusion

This entry aimed to explore the perceived affordances of connectivist tools for a Higher Education Postgraduate Diploma course. The auto-ethnographic data of the author of this entry corroborate Bryant et al.'s (2014) observation that the use of connectivist tools can make a significant contribution to learning through their affordances which enable social interaction, connectivity, and support of collaborative practices. However, the adoption of connectivist tools may be thwarted on both an institutional and individual level if the perceived affordances of these tools are not made explicit and if personal and professional boundaries become too blurred (Bryant et al. 2014; Madge et al. 2009). The core assignment on this course was designed in such a way as to encourage the creation of a product by the group of higher educators who were part of the interinstitutional PG Dip teaching and learning course through the use of social media platforms such as Google Drive. However, if the affordances of connectivist tools such as WhatsApp, Google Drive, and Skype are to be actualized for educational purposes, they must be accompanied by effectivities of academics and students in terms of their abilities to recognize and use the tools for teaching and learning.

Synonyms

Agile methodology; IT education; Kanban; Project work; Scrum

Introduction

In recent years, the world has become much more complex and unpredictable. A special acronym “VUCA,” meaning “volatile,” “unknown,” “complex,” and “ambiguous,” has even appeared to describe it. The situation changes unexpectedly and rapidly, the crisis becomes the norm of life, and the rate of change inexorably increases. In modern management, the implementation of projects that respond flexibly to the demands of a volatile market is receiving increasing demand.

This VUCA world requires employees able to apply Agile principles to their work. Training in the Agile approach has become common for employees and leaders of large companies but also the governments such as Norway and New Zealand. Agile method education has been introduced at many universities including Cornell University and Northern Arizona universities.

Definition

The word “Agile” has many meanings. The English dictionary definitions include:

- Quick management (Gaponova and Kulin 2016)
- Flexible management (Evseev et al. 2016.
- Active, surviving (Chernykh 2008)
- Agile, lively, fast, moving (Babaev 2016)

By studying the current literature on the Agile topic and opinions of professional experts, it is concluded that there is no precise definition of “Agile” methodology in project management. So it is necessary to consider the most vivid variants of the term “Agile.”

Gaponova and Kulin write that Agile represents flexible management that reacts quickly to changing meso-, macro-, and mega-changes and adjusting economic policy in accordance with changing conditions (Gaponova and Kulin 2016).

Talking about Agile software development, it is a range of different incremental and iterative software engineering methods that are advocated based on an “Agile philosophy” mentioned in the Agile Manifesto (Fowler and Highsmith 2001).

The iterative approach involves splitting the project lifecycle into a series of iterations, each of which resembles a “mini project,” including all phases of the software lifecycle in application to creating smaller fragments of functionality, compared to the project as a whole. The goal of each iteration is to get a working version (release) of the software, including the functionality of all previous and current iterations. The final iteration result contains all the required functionality of the product. Thus, with the completion of each iteration, the product develops incrementally.

Lifecycle of this model allows to classify this model as iterative and in terms of product development – incremental (Defazio et al. 2014).

It is worth noting that Agile software development methods first appeared in the early 1990s, and IT companies were the first to show interest in this methodology. Many of these companies were interested in Agile methods and its application in the companies (Jovanovic et al. 2017).

The use of Agile software development led to changes in the project work in companies, as well as in the results of project implementation, which is a significant advantage of this approach in comparison with traditional (Dingsoyr et al. 2012; Stettina and Hörz 2014).

Considering the various tools of project management, Agile methodology emerged as the first of them, and other tools were formulated on the basis of it.

The most famous for this philosophy was after the adoption of the “Manifesto of a flexible methodology for software development” (Agile Manifesto). This document contains the basic principles that are characteristic of Agile philosophy in project management.

The main ideas of the Agile Manifesto are as follows:

- Individuals and their interactions are more important than processes and tools. In other words, the project team in the Agile philosophy is much more important than the formalization of the processes, because the results of the project depend on it.
- Running software is more important than full documentation. This principle suggests that it is more important to create a working product that fully meets the needs of the client than simply perform a number of works under the contract, not paying attention to the result itself.
- Cooperation with the customer is more important than contractual obligations. It is more important to communicate with the customer and clarify the contentious issues, than work under the contract.
- Responding to change is more important than following a plan. This is also an important principle, because Agile philosophy is a flexible methodology that allows for easy changes to the project, despite formal requirements (documentation, contracts, etc.). During the project, the customer can make adjustments to the product, and the project team accepts these changes.

The Agile Manifesto was written in 2001 even though the start of Agile methods can be traced back to 1957 (Larman and Basili 2003). In the mid-1990s, the so-called “light methods” of project management appeared as an alternative to “heavy methods,” such as the V-model, the cascade model (Waterfall), and various variants of the stage-gate models. Such models were called “heavy” because of a large number of necessary project documentation, a lot of formal control procedures, and

verification of project implementation, which significantly complicated the design work and extended the implementation period. Therefore, the authors of the Agile Manifesto decided to fix the principles of work on Agile flexible methodology in one general document (Grimheden 2013).

Evseev et al. in their article note that Agile defines the basic values, rules, and principles on which flexible project management methodologies are built, such as Scrum, Kanban, Lean, and others. The presented methodologies can be used both together and independently of each other. Refactoring, iteration table, sprints, retrospective, quick meetings, division into roles, etc. are all tools that can be implemented in any project team where the Agile approach will be applied (Evseev et al. 2016).

Speaking about the application of Agile in the IT field, a flexible development methodology is implied as a series of approaches to software development based on the use of iterative development and the dynamic formation of requirements and ensuring their implementation as a result of constant interaction within self-organizing working groups consisting of specialists from different fields (Lopatin 2012; Ildemenov 2016).

Akmaeva et al. argue that the Agile methodology is a set of approaches to software development that is built on the principles of teamwork, speed, lack of formalism in communicating with the customer, and flexibility in changing the initial plan of action (Akmaeva et al. 2017).

Agile is a time-boxed, iterative approach to software delivery that builds software incrementally from the start of the project, instead of trying to deliver it all at once near the end (<http://www.agilenutshell.com/>).

Martin Christopher says that Agile is a system of building work in the company, which makes changes in organizational structures, in information systems, in logistics processes, and in the way of thinking of employees. Flexibility is the main characteristic of such businesses. Indeed, the origin of flexibility as a business concept lies in flexible production systems (FMS) (Christopher 2000).

Another significant definition was given by Fowler and Highsmith that Agile software development is a set of iterative and incremental methods of software development that are promoted on the basis of the “Agile philosophy” captured in Agile Manifesto (Fowler and Highsmith 2001).

Despite the fact that in the main repackaging and re-branding used to be well proven in the development of good software, flexible movement can be considered as an alternative to the so-called traditional methods of software development. Traditional methods focus on pre-planning and strict change management, but flexible methods have been developed for adoption and effective change management (Highsmith and Cockburn 2001).

The Need for Agile Methodologies

The two most popular Agile methods are Extreme Programming (XP) and Scrum (Hamed and Abushama 2013). Scrum is a method focused on the point of view of project management on flexible development (Schwaber and Beedle 2002), appointment of time, continuous tracking of project progress, and customer focus. The XP development method is a set of practices to ensure effective gradual development. In practice, many flexible development projects combine them in two ways (Dikert et al. 2016).

There are several methodologies for project management. The most widely known and long used is the cascade model (waterflow approach). It is defined as the work flow, passing the successive phases of analysis, design, implementation, testing, integration, and support (Evseev et al. 2016).

This model is more suitable for large projects that are performed for a long time with the involvement of a large number of employees of different positions and functions. It is important to note that the distinctive feature of the cascade model is the execution of each next stage after the previous one has been performed.

Consider the main advantages of using the waterflow approach. Such a project is easily controlled by the customer due to the rigid

formalization of all processes, where each type of work is transparent and consistent. In addition, such transparency leads to more cohesive teamwork due to the fact that each team member knows his area of responsibility and the task pool, which also positively affects the success of the whole project. Such rigid management of the project allows you to accurately estimate the cost of the project and each of its individual stages and determine the timing of each task. This allows you to forecast the necessary costs and financial benefits from this project.

Each methodology of project management is not ideal and has its drawbacks. The main negative point in the cascade model is the lack of flexibility when making changes to the project. Hard formalization of all processes does not allow to quickly changing the elements of the project, which negatively affects the time of its implementation. Even the slightest changes require the whole project or part of it to stop before making the necessary changes to the project documentation. Many project management experts criticize this cascading approach for excessively formal project management, which adversely affects the timing of its implementation, the budget spent, and the quality of the finished product (Evseev et al. 2016).

History of Agile Methodologies

Approximately 10–15 years ago in IT sphere, there appeared another methodology of project management – Agile methodology or spiral model.

Initially, it was thought that the way to production flexibility was provided by automation in order to ensure a rapid change and, thus, greater responsiveness to changes in the range or product volume. Later, this idea of production flexibility was expanded in the broader business context, and a concept of flexibility as an organizational orientation emerged (Christopher 2000).

Agile methods were originally intended for usage in small projects with a single team (Boehm and Turner 2005). However, its demonstrated and potential benefits made them attractive

beyond this context, especially for large projects and in large companies. This is despite the fact that they are more difficult to implement in big projects. Compared with small projects that are ideally suited for rapid development, larger ones are characterized by the need for additional coordination. A particular problem with large projects is how to handle coordination between teams. Large-scale flexibility is associated with additional problems in dealing with other organizational units, such as human resources, marketing and sales, as well as product management. In addition, large scale can lead to the fact that users and other interested parties will be removed from the developers. Despite these known problems associated with large-scale flexibility, there is an industry trend toward the introduction of flexible methodologies in general (Dikert et al. 2016).

An important question is raised by many researchers as to what benefits the team or company receives from the use of flexible technologies. According to the 11th Annual State of Agile Survey, the companies get the following benefits from Agile application:

- Ability to manage changing priorities. In today's rapidly changing world, this characteristic is one of the keys for these companies.
- Quickly make changes in the business processes in the company according to the new data from the market. Agile allows flexible companies to remain on the market and be ahead of competitors.
- Increased team productivity.
- Improved project visibility.

Agile methods become the most commonly used in the software industry. Annual surveys have shown that the use of Scrum has increased over the past few years. According to the Annual State of Agile Survey, in 2016, the percentage of respondents' organizations that practice Agile amounted to 94%.

Knowledge of Scrum is critical for most companies, as it emphasizes the importance of team effort and social activity in software development. Scrum is often used in project management

projects and includes monitoring and support, which provides transparency (Mahnic 2011; Coupal and Boechler 2005). This advantages allow the use of Scrum reducing the gap between the skills taught in academic contexts and the requirements imposed on the software industry (Rodriguez et al. 2015).

With the growing popularity of Agile software development methods, the software community has faced a new challenge. Most Agile methods “pay very little attention to overall architectural activity” (Babar 2014). For example, Kent Beck views architecture as emerging and evolving in everyday design (Beck 1999). Kruchten et al. predict that “the software architecture will be recognized as a key basis for Agile software” (Kruchten et al. 2006). The question of how much architectural effort is required in flexible projects was rated as “the second, burning issue facing Agile practices” (Freudenberg and Sharp 2010).

The relationship between Agile methods and the software architecture in education has not been sufficiently studied in the literature. Cleland-Huang et al. represent an approach to the study of software architectures in Agile projects in education (Cleland-Huang et al. 2014). This approach focuses on the design phase of the architecture in Agile projects and, in particular, on the role of stakeholders, but does not affect the actual dynamics of this Agile project (Angelov and Beer 2017).

Angelov and Beer (2017) present an approach to the implementation of software architecture in Agile education projects and share our experience with two successive application approaches. The strategies chosen for the implementation of architectural measures proved to be mostly effective. Using our approach, students perceive the value of architectural actions and view the access as an addition to the Agile software. They appreciate the avant-garde activity in building architecture, although they perceive it as a slight deviation from flexibility. The realism of this approach requires additional attention. It was applied mainly to architecturally savvy software, while in practice, the software often does not understand or appreciate the architecture activities performed in the

projects. In the future work, it is necessary to study the types of problems that an architect and Agile teams face when working with architecturally uncoordinated software and the approaches they can perform to facilitate them (Angelov and Beer 2017).

Teamwork is one of the key competencies that students must acquire to be competitive in the labor market, as enshrined by the European Higher Education Association (EHEA) (Noguera et al. 2018). The ability to work in groups is of particular importance, since today many tasks are too complex and too large to be performed by one person. Many studies show that the use of teamwork in learning increases students’ motivation to gain new knowledge and experience (Laux et al. 2016). Students have to learn to cooperate fruitfully with each other and to independently organize work in group (Miller and Hadwin 2015; Tseng and Yeh 2013).

The flexible methodology of Agile project management is becoming very common in tertiary education. Lecturers advance Agile methodology, especially a scrum in educational process that will allow students to use the gained knowledge in practice in the real companies (Scott et al. 2014).

Many large companies note importance of training in Agile methods at various business schools. The strategy of large companies such as British Telecom and IBM is directed to use of flexible technologies in all business (Grout and Bonham 2012). This is also true of many companies not in the IT sphere who also actively apply Agile principles of work in the business. It is possible to give the Government of Great Britain (the review of the NAO 2012), the US Government (the report of GAO 2012), the banking sector as examples (Sarran 2012), the pharmaceutical industry (Fitzgerald 2012), and many other branches (Cubric 2013).

Agile Methodologies Course Example

Kropp and Meier have conducted survey of 103 students to understand the efforts they spent in projects for project management, programming of a product, and drawing up necessary

documentation (Kropp and Meier 2013). The result of the poll has shown that a lot of time and work has been spent for management and documentation preparation. Also students have noted that during implementation of student's projects, they have gained much more knowledge and competences, than at ordinary lectures that has also positive effect in educational process.

Besides these competences, flexible values which are sounded in the Agile Manifesto (<http://agilemanifesto.org/>) are important. The mutual respect, openness, and courage are examples of such flexible values (Kropp and Meier 2013).

The course on program engineering on Agile methodology which is submitted in the work of Kropp and Meier can be an example of the application of Agile education. This discipline was carried out for students of a bachelor degree and lasted one semester (16 weeks) with a total of 120 h. The number of students was 27 people. Within the course, a 2-h lecture for all students and a program seminar for a half of students were given every week. Work is implied in teams from six to eight people. The complete project of programming Java created with the use of flexible methodologies was the result of the development of a course.

In the part one titled application engineering the practical – at the first two lectures has been given to students' introduction to extreme programming (XP). The extreme programming and Agile Manifesto methods were discussed. In seminars, each student has finished assessment of coding and has received comments.

While the students were working individually or in small groups in part one, part two was different – the Agile game was played in the classroom. The students must be members of a "real" scrum team to really understand how scrum works. Since this is not possible in the classroom, the scrum team was simulated in the student project. The student project purpose was to develop a 2D computer game applying all needed engineering practices. The students worked in four scrum teams of six to eight. Each team was free to decide what kind of computer game they wanted to develop. One student was voted scrum master;

the lecturer was the product owner. The teams completed six 1-week sprints. Every week during the workshops, each team did the sprint planning, sprint review, and retrospective coached by the lecturer. During self-study, the students developed the actual game. In the last week, all the teams could demonstrate a working game.

Agile values (Agile Manifesto) are difficult to teach. The approach in this course was to present to the students that these values are not just something the developers of the Agile Manifesto intended to give lip service to and then forget. They are working values. The Agile value concepts were introduced in the first part. Usage of the values was propagated in the second iteration through means like retrospectives, common code ownership, or pair programming. Many discussions during the lectures and workshops tried to transport that message (Kropp and Meier 2013).

Development of an Agile training course is also important process in the higher education since depends on competently built course knowledge and skills of this approach gained by students.

Ingrid Noguera et al. describe creation process of such subject matter in the work. Two online and three personal meetings have been held for construction of the new training course. An important point is Google Drive usage and the Dropbox instrument for sharing the files in the course of creation of documentation of a new Agile course. After definition of the new scenario, the introduction process has begun in autumn and spring semester of academic year 2015–2016. The new course has been tested during two consecutive semesters. After each iteration, the design was estimated on the basis of notes and opinions of the teacher (collected through two interviews) and opinions of the students (who are brought together through two polls held at the end of both semesters). Based on assessment, minor changes have been applied to design which have been simply directed to providing more accurate recommendations for students (Noguera et al. 2018).

In 2011, in KTH Royal Institute of Technology, Switzerland, it was offered to five student's projects on mechatronics to use a scrum in implementation of projects. 37 students, 5 companies,

and 10 teachers have participated in this experiment. In total, five design teams have been organized. The working product prototype has acted as a result of project work of college teams. The application of an Agile methodology in project work of students teaches bigger flexibility to cope with a difficult task when developing a product in the sphere of mechatronics. Besides, flexible methodologies allow carrying out IT projects quicker and more qualitatively. Universal introduction of an Agile and scrum at the university is complicated by complexity of refusal of the traditional work principles of design team and the fact that mainly flexible methodologies are used when developing IT projects today (Grimheden 2013).

Cubric in the entry gives an example of Hertfordshire Business School where since 2007 the discipline “Flexible project management” within training of masters in the sphere of project management has been entered. The main course objective is providing to students practical experience of application of flexible technologies. Within this discipline to students offered to create the Internet the page on training in flexible approaches, using the Wikipedia platform. In total, the project has included five iterations (sprints), and each sprint lasted 2 weeks. In each design team are cast as follows: one student carries out a role the master’s scrum (scrum master is appointed by other team participants), and the others are performers. The scrum master’s role consists in ensuring effective teamwork, carrying out regular sprints, and preparing reports on the done work at the end of each sprint.

Within the next 3 years, students gave feedback about this course specified by positive sides of discipline – regular and operational feedback about the project implementation, the interest of the teacher in a subject, and a practical orientation. One of course problem is unavailability and inability of some students to work in team that is implied by flexible approaches (Cubric 2013).

Erturk and Mac Callum (2015) have presented in their article interesting ways of flexible technology application in the educational program of IT specialties in a higher educational institution in New Zealand. In the first case it is described how students acquainted with flexible practice within

discipline the system analysis at which more than 30 students studied.

The second research was directed to applying of practice within discipline the user interface where flexible Agile methodology has been used for assessment of course passing.

The main motivation of such experiments is to acquaint students with flexible approaches and to show that they can face them in practice, in the real company. Therefore, it is necessary in advance to study and try to use what will be applied in future work of students.

Therefore, the lecturer used this course as an opportunity to acquaint students with some concepts and approaches of flexible development in branch. The purpose was not in completely to imitate Agile, and it is rather to give to students the chance to see how these methods can be built in system development. The main attention was concentrated on studying and use of the UX/UI methods, while they have also tested how flexible approaches can support its work (Erturk and Mac Callum 2015).

Kamat and Sardessai present the principles to the Agile Manifesto adapted for use for flexible approaches in education in the article. Their option of the principles of this code looks as follows:

- Teachers and students are much more important than administration and infrastructure.
- The competence of the team and their cooperation are more important than observance of regulations and the competition.
- The involvement into work and competitiveness of a product are more important than the plan of work and the set indicators.
- The relation to the project and skills of training are more important than abilities and education (academic degrees).

The flexible manifesto in education can be applied in all main spheres of educational activity with assistance of ICT. It is expedient to teach some disciplines to students of different specialties. For example, the course on geometrical modeling could be taught in common in the field of computer sciences, mathematics, and

mechanical engineering faculty. All cooperation has to be facilitated by means of a learning management system (LMS). At the same time, students can find all training materials on available free resources in the Internet that unifies a discipline course. It is promoted by appearance of the Web 2.0. In that case, teachers can spend more time for practice.

Also Kamat and Sardessai declare in their article that it is necessary to approach modern information technologies in the training course, for instance, to suggest students to pass the small test on the passable material on their phones at the beginning of the occupation. Thereby, the student's motivation to digestion of material increases. In general, authors say that it is important to transfer all system of the higher education to the flexible half-courses and to take modern IT tools (Kamat and Sardessai 2012).

Pozenel and Mahnic describe how the checklist was used for design of empirical studies with students (ESWS) at computer and information sciences faculty at the University of Ljubljana, Slovenia, for the purpose of assessment of two most widespread methods of flexible assessment, that is, planning poker (PP) and team estimation game (TEG). The research is conducted within a training course on the development of the software in which students have to work in teams to develop the project, strictly following Scrum.

The capstone course at the University of Ljubljana teaches students to the software flexible development, in particular scrum, on the basis of practical command projects. The course lasts 15 weeks and is accepted by student's information scientists in the last (sixth) semester. Students have to work in groups to develop the real project on the basis of requirements of the users provided by the expert of the domain playing a role of the product owner.

The course design is based on scrum structure and consists of four sprints. The first sprint (which is also called by Sprint 0) lasts 3 weeks and serves as preparatory sprint prior to the project beginning. Other part of a course is divided into three regular sprinters of scrum sprint (Sprint 1, Sprint 2, and Sprint 3), each of which lasts 4 weeks.

During Sprint 0, there take place official lectures to teach students of scrum and how to apply the user stories to the requirement specification and project planning. These 3 weeks are also used for acquaintance of students with the initial product lag containing a set of priority user stories for the project which they are going to develop. At the end of Sprint 0, each team estimates the efforts necessary for realization of each history of users and prepares the plan of release.

Sprinters 1, 2, and 3 are regular sprints which have identical structure. Each sprint begins with a meeting on planning of sprint in which students report about the content of the following iteration with the product owner and develop the initial sprint backlog version. During the sprint, every team should get together at meetings of daily scrum regularly and to support their lag from sprint, while at the end of each sprint, reviews of parley and retrospective meetings of sprint are held. At a general appointment, students present the results to the heads, and at a retrospective meeting, students and heads forgather to discuss development process in the previous sprint in which suggestions for improvement in the following are offered (Pozenel and Mahnic 2016).

If to speak about Russia, then there is no practice of application of Agile in the university environment now. Certainly, not all problems in education can be solved with the help of flexible methodologies. For example, at the university, it is possible to build work of scientific and educational groups or design and educational groups; it is possible by means of methodology Agile. Also flexible methodologies perfectly are suitable for a design seminar where students work on the projects. An important part of educational process of all students is preparation course and theses, work which can also be built with use of collaborative technologies. Also flexible methodologies can increase productivity of work on applied projects of external customers at the university thanks to harmonious work of team and continuous contact with the customer.

It is important to remember the organization of scientific activity at the university. Flexible technologies can be applied at the organization of work on preparation of the application for a

grant, when carrying out joint scientific research, including with foreign colleagues. Also Agile methodology perfectly fits into the organization of work on writing of joint articles, monographs, and textbooks in co-authorship.

Impact of Agile Methodologies in the Classroom

The course to an Agile at the university especially on IT specialties is obligatory discipline in the modern world. Before development of a new Agile course for program engineering, it is important to define competences which need to be developed at students in the course of studying of a course. Such competences can be divided into three categories.

First of all, it is technical skills. Their development forms a basis for development of the high-quality software. Engineering practitioners who especially carefully accustom to extreme programming are also important and include modular testing, clean coding, test development, collective possession of a code, and others. Engineering practitioners are competences which accustom everyone the person individually.

Also important competences are flexible management methods. Agile project management defines as projects on flexible technology are formed and started. Flexible methods of management include iterative planning, the short release periods, strong participation of clients, and highly intellectual and motivated teams. Management social competences are extremely important in the process of Agile methods development to form team and adjust work.

Summary

The cases cited in the entry show the applicability of the methodology in the educational environment and not only in the teaching of computer technologies.

Using Agile tools allows students to save time on developing a new product and improve

interaction between team members, which leads to increased productivity.

Thus, the methodology should be shifted not only to teaching computer sciences but also to other educational programs, where the design type of instruction is applied.

Software Engineering and Information Technology Curricula

Information technology and software engineering education curricula incorporate training in programming and computer technologies, as well as basic science skills. As information technology is always applied in organizations, skills related to organizational understanding, business and interpersonal relationships are gaining more emphasis when the extent of systems grows. Competencies required from software developers are getting wider; developers are expected to understand the lifecycle of the products from early planning to design, implementation, and maintenance. The concept of systems development life cycle was introduced around 50 years ago, and since then information systems have evolved from individual entities to interconnected webs of technologies, data, and software. Understanding current technological and information environments is an enormous task that maybe no one fully masters any more. Educational institutions strive to provide skills and tools that help in this constantly growing and evolving challenge.

Although education standards vary from country to country, the international and global character of software development enforces certain amount of unity in training. Same tools and programming languages are used all over the world, and many large systems development projects are divided between many locations and countries at the same time. Even though there are some

systematic differences in the working habits and organization of the work between cultural areas, global requirements for collaboration challenge them. Outsourcing to distant countries has become standard in software work, and differences are doomed to narrow. Organizations with low hierarchy that allow employees a good degree of self-determination will be best candidates to apply agile methods, which are becoming the new standard of software work.

Competence Requirements from Industry

What are the essential industry skills in software engineering or information technology? The UNESCO global report on the status of engineering 2010 discusses engineering education, which has developed worldwide towards similar overall practices (UNESCO 2010). According to the report, there seems to be a wide consensus on main goals of engineering education.

Accreditation bodies define information technology and software engineering competences broadly to accommodate the variation of educational institutions and programs. For example, the list of goals by ABET in the USA remains the same in the last decade (<http://www.abet.org>). ABET includes in the student outcome requirements for any engineering program general science and technology skills, research skills for conducting and analyzing experiments and data, and an ability to formulate engineering problems. Moreover, engineers need to be able to consider also constraints such as economic, environmental, social, political, ethical, health and safety, manufacturability, and sustainability, and to act ethically. Particular working life skills are listed as an ability to function on multidisciplinary teams, and to communicate effectively. The UNESCO report on engineering mentions similar capabilities, referring to a many other organizations and accreditation bodies (UNESCO 2010). The question remains, however, how these goals are attained within various educational systems.

Dialogue with companies has revealed that ICT education had failed to fully respond to the current requirements in the software industry despite existing standards (Holvikivi et al. 2017). Demands from companies increasingly

stress capabilities for collaboration, efficient team work, and professional communication. Moreover, feedback from software industry has confirmed some of the points previously mentioned, such as the ability to function on multidisciplinary teams and the ability to communicate effectively are needed, but there is also need for negotiation skills, and, specifically, a need to understand development processes. The fast changes in development practices need particular attention.

Teamwork and Group Processes

Groups play a critical role in people's lives, and in particular, in contemporary business environments, teams occupy a central role. Teamwork and groups are mainly studied by social and organizational psychology. In his review of current status of research in group processes, Levine (2013) emphasized that the amount of accumulated research is enormous, and the interest has not shown signs of decline because of the great importance of social aspects of group processes in organizations. Some of the most important findings regarding group processes that are relevant to student teamwork, agile development practices, and education are presented below.

Perhaps the most essential research finding is the importance of mutual trust in the team. Groups perform better when their members feel accepted and comfortable in the group. Certain personal factors influence this, namely interpersonal attraction, as well as individual characteristics of group members such as openness to experience. The degree to which the rest of a group agrees with each member about who he or she really is has an impact on the feeling of comfort. Moreover, mutual support and leadership improves group cohesion. The leader of the group has a crucial role in taking a visionary position and inspiring people to follow. Additionally, group performance is affected by a number of task related factors, such as the complexity or difficulty of the tasks, routineness, or autonomy.

Creative groups need to aim at internal synergy and to overcome the factors related to production loss in groups such as social loafing, evaluation

apprehension, production blocking, and downward comparison. One of the means is to ensure that group members are held accountable for their individual contributions to the group. Moreover, group members should feel free to express their ideas as they occur without fear of others' criticisms, and members must be motivated to process information from other members. Diversity within group usually is beneficial for its creativity. Factors which enhance the benefits of diversity are a generally supportive social context and a longer time working together as a team. Research has proven effectively that successful real-world collaborative groups have a common vision and set of values. When the composition of a group is changing in one way or another, even when the members remain the same, it requires renegotiation of the interpersonal relations from time to time.

Student Teamwork

In case of student project groups, the composition of the group is often one-time only, and the members might not know each other previously. To ensure that a transformational leadership and mutual trust in the team are formed, instructors have to support the teams in the beginning. Establishing a leadership position and gaining authority in a team tends to be difficult for students in a peer relationship. Even later, teams require monitoring and facilitation that prevents social loafing, free-riding, and negative interactions within the team. One way to encourage equal contribution to the projects is to organize a mutual evaluation at the end of the project where students are individually requested to indicate how much each team member contributed to the project.

Teamwork and project work are more challenging to evaluate fairly than individual deliverables. Larger teams such as six or seven students are more problematic in this respect. Most often teams of four are the ideal solution also for team efficiency. Moreover, a regular presence of teachers in the classroom gives them an understanding of each student's skills. Also, virtual environments such as Trello and GitHub follow individual contributions.

Teacher Competences in Team Teaching

Multidisciplinary courses built around real-world problems provide one possible way of helping students to improve their communication and group working skills in an environment resembling actual work life situations. These kinds of courses are by definition being designed, conducted, and evaluated by a teacher team as opposed to a single subject matter teacher. At many universities, teachers are used to being the only teacher responsible for the course. Teaching staff with industry experience has learnt teamwork in practice, but for purely academic staff, the change required to work efficiently in a team of colleagues might be challenging. This change is profound as it is not just a method or single skill, but it actually changes the whole culture of teaching. Actually, this new challenge for teachers to be able to work productively in collaborative teams is similar to the requirement set by the changed working life for their students. It could be considered a legitimate requirement for teachers to follow the same practices they expect from their students (Vesikivi et al. 2018). The method requires that teachers have an open mind and are ready to face uncertainty. Teachers need to have enough professional experience and confidence when they start collaboration in this format.

Collaborative Problem-Solving and Project-Based Learning

Collaborative problem-solving and project-based learning are considered central methods to educate present day engineering students, because they simulate challenges that the students will face in professional work, such as open-ended assignments, uncertainty, and coordination of collaborative efforts. Numerous implementations of project-based learning have been reported in various countries in recent years. Even though the theoretical backgrounds of these efforts differ, the practical implementation usually follows similar patterns on applying a project development cycle to course work and concentrating on the problem and its solution instead of listed curriculum items (contents, skills, competences).

One of the well-known systematic efforts towards project-based learning is the global CDIO initiative that has united a number of engineering institutions around a common curriculum structure worldwide (Crawley et al. 2007). Another global model which extends beyond engineering to other academic fields is led by the Aalborg University in Denmark. Edström and Kolmos (2014) compared these two models and found them to be mutually complementary rather than competing. The CDIO model includes one project in each academic year, whereas the PjBL model followed in Aalborg is totally based on thematic project courses. Numerous other successful implementations of project-based learning methods have been reported in various countries in recent years, building a large body of evidence for their favor.

In the CDIO syllabus, personal, professional, and interpersonal skills include engineering reasoning and problem-solving, experimentation and knowledge discovery, system thinking, multidisciplinary teamwork, and communication (Crawley et al. 2007). When the learning is organized between members of a collaborative community combining theory, creativity, progressive inquiry, and practice, it profoundly develops student understanding (Lakkala 2010).

History of Systems Development Methods

With the increasing capacity of computer hardware, and development of high-level programming languages, application size grew fast in the 1960s. The maintenance and control of new large software modules required software development methods that were later called software development life cycle (SDLC) or systems analysis methods. The first methods were built for managing large mainframe software applications such as statistical, insurance, and banking systems, not to forget military applications. The software engineering methods emphasized structural, controlled processes, and extensive documentation, and were coupled with project management methods. The development work

was divided into distinct phases, which is referred to as the waterfall model: defining business requirements, system analysis, design, coding, testing and evaluation, implementation, and training and maintenance. Each phase has fixed deliverables, milestones, and measures that mark its completion and move to the next phase (Encyclopedia of software engineering 2002).

The basic waterfall model led to development of CASE (computer-aided software engineering) tools in the 1970s to smoothen the development work, and methodologies such as UML in the 1990s, the visualized unified model that is tied with object-oriented programming. However, when systems became even more complex in networked environments, and particularly the new application types appeared in the internet, the waterfall model was used in more creative and flexible ways, including prototyping, iterative, and incremental development.

Agile and Scrum

Software engineering has encountered methodological crisis in 1960s and again in 1990s because of the complexity and long development time of large applications. In 1994, it was estimated that over 80% of the software projects encountered delays and exceeded their budgets. The Agile Manifesto in 2001 (<http://agilemanifesto.org/>) was a culmination of the frustration on heavy long-lasting projects. It condensed the alternative views into a list of 12 principles:

1. Customer satisfaction by early and continuous delivery of valuable software
2. Welcome changing requirements, even in late development
3. Working software is delivered frequently (weeks rather than months)
4. Close, daily cooperation between business people and developers
5. Projects are built around motivated individuals, who should be trusted
6. Face-to-face conversation is the best form of communication (co-location)
7. Working software is the primary measure of progress

8. Sustainable development, able to maintain a constant pace
9. Continuous attention to technical excellence and good design
10. Simplicity – the art of maximizing the amount of work not done – is essential
11. Best architectures, requirements, and designs emerge from self-organizing teams
12. Regularly, the team reflects on how to become more effective, and adjusts accordingly

Agile methods are based on four broad values derived from the Agile Manifesto: individuals and interactions, customer collaboration, working software, and response to change. These values are common to all major forms of agile methods such as Scrum, Extreme Programming, Lean Software Development, and Crystal. The agile way of working includes short development cycles that are called sprints and constant interaction between the development team and the customer. It is best suited for web projects where requirements tend to change quickly, and goals are not very clear in the beginning. Therefore, agile methods were first adopted by smaller companies with smaller projects. However, currently, even the largest software and ICT companies, such as Accenture, Microsoft, Nokia, and SAP, claim to apply agile practices in their work.

The various methods to apply agile development typically include sprints that last a week or two and scrum as project management method. In scrum, small stand-up meetings are held daily to check the current progress and assign new tasks. Moreover, scrum includes a few roles such as scrum master and product owner. A sprint has a task list from where team members pick their tasks after they have finished the previous one. After the sprint cycle, there should be a product prototype that can be evaluated, and further decisions made based on the delivery. Short cycles allow changes in requirements and close monitoring of costs and other resource use.

Lean and Kanban

Lean manufacturing and kanban were developed in Japan for Toyota, and their idea is to simplify manufacturing process by eliminating all waste,

minimizing inventory and process time. In software development, kanban cards are used for tasks, and they will contain a backlog for the project. Use of kanban cards has exploded in all business areas with the availability of simple online products such as Trello or Asana.

Experiences Form Agile Courses

Agile software development has replaced former, highly systematic project management practices in many areas of the software industry. Software development has changed drastically during the last decades. Individual coding or testing in large projects still exist, but most developers have to be able to co-operate in diverse teams and to apply flexible working methods. Many studies have shown that agile methods are already mainstream in the industry (Kropp et al. 2016). However, the incorporation of the tremendous changes in development practices has entered academic education rather slowly.

First efforts to include agile methods to higher education were made more than a decade ago, and currently, separate courses on agile development are widely offered as part of software engineering curricula (ibid 2016, Mahnic 2012). However, actual use of agile methods as educational practice is less common even though a widespread use is presumably on the brink of breakthrough. Agile development can be applied in many kinds of project-based learning courses by replacing traditional project management with flexible practices and sprints, and by replacing formal meetings with scrum meetings. Compared to traditional project management methods, this way allows more development cycles and therefore enables the completion of a functional prototype during an academic module.

The literature on agile methods in education presents largely three different ways to approach the subject. First, as any other subject, project management can be lectured and knowledge tested through examinations. Nevertheless, this method does not address the development of interpersonal or organizational skills.

Secondly, agile methods can be introduced through a project course, where they are practiced in an application development project. There are many examples of innovation and multinational application development projects, where the agile approach and teamwork function as a backbone, even though not necessarily explicitly expressed. The EU has sponsored Erasmus intensive programs that include universities from several countries and require a preparation phase over distant education tools. In this kind of international efforts, where virtual learning environments are an essential part of the course, students and teaching staff from various universities need to adapt to changing and unexpected learning settings.

Positive experiences have been reported particularly from capstone courses where students are assumed to have already strong technical skills and involvement of real customers is possible (Mahnic 2012). Moreover, agile working methods have been studied in multicultural groups, and in courses on software business, reporting promising outcomes. However, it remains unclear whether negative cases have been reported to the same extent as positive outcomes.

A quick introduction to agile, user centered way of developing product ideas is presented by Google Ventures Sprint (<http://gv.com/sprint>). Even though it is mainly designed and applied for real business settings, the 1-week framework makes it a suitable way to introduce the main ideas to a student group. Because it is very much hands-on, practice centered, it gives a quick immersion to creative IT work.

The third, most immersive method extends beyond agile courses, where agile work has been expanded to the entire curriculum. Agile approach is more than a subject of study; instead, the methods in course design and implementation are based on agile ideas. In this approach, the schedules of modules are not defined in strict detail in advance; instead, the planning is flexible and done in small increments during the implementation (Holvikivi and Hjort 2018).

Case Example: Simulated Work Placement

Metropolia University of Applied Sciences offers a bachelor of engineering degree in information

technology. Part of the degree is a 3 month internship in a company. Sometimes students fail to find a real employer for their work placement. A simulated workplace environment was created to give students chance to practice internship in this kind of situation. Fourteen students participated working full time as interns in a designated office space inside the school building during 3 months. They received an order from a publishing company that wanted to explore alternatives for a new product. The work was organized as an agile project, which emulated real workplace conditions. The project group held regular scrum meetings every morning where teachers participated as needed. In a scrum meeting, all participants stand up and explain briefly what they have done since the last meeting, what they intend to do next, and what kinds of problems they face.

A working life experience should teach project management and team working skills in addition to technical skills. Because of a real customer, students started understanding what making a commercial product entails, and how user needs are incorporated in design. The scrum development project was a new method for the participants. In the beginning, the group held scrum meetings every day in the morning. First, teachers were involved to show the method, set up timesheets for work, and comment on student achievements and plans. Three weeks later, teachers let the team divide into technical and user interface groups that were self-regulating. Students were allowed to decide how often they need scrum meetings and stopped holding them daily. Soon they noticed that having fewer meetings did not facilitate the process (Holvikivi and Hjort 2018).

Case Example: Software Engineering BSc Curriculum

The software engineering curriculum for bachelor of science in the Metropolia University of Applied Sciences in Finland went through a fundamental change in 2014 (Holvikivi and Hjort 2018). Project-based methods were included into most modules in the new curriculum. Additionally, the concepts of progressive inquiry and problem-based learning were applied in course design. It

was assumed that it would be most efficient to start with open-ended problems immediately at the beginning of studies. Moreover, participatory online learning environments were used to support the learner's development of understanding through collaborative construction of a shared product (Lakkala 2010).

The first study year was divided into four successive 15 ECTS modules 8 weeks each. Each module had a theme that introduced the different IT subjects students could major in: networks, media and web-development, electronic devices, and software engineering. The project in each module was supported by a varying amount of basic and theoretical studies such as mathematics and physics.

In an integrated module, all professional and language content (communication skills) was integrated apart from the separate science classes. The teachers collaborated both in theoretical subjects and project work. Deliverables such as presentations and project documentation were assessed both on substance and communication aspects. Some types of lessons with practice usually had more than one teacher present. Also during student team presentations most teachers attended, gave feedback and evaluated deliverables together.

The integrated modules that applied an agile approach were Orientation and Games (programming) in the first year, Application Development Methods in the second year, and Software Business Start-up in the third year. They were largely similar in design, lead by nearly the same teacher teams who applied agile practices in the planning of instruction.

The Games module was actually an introduction to Java programming. In the beginning of the module, students attended some lectures in programming and completed a large number of programming assignments in a MOOC setting. The MOOC (massive open online course) was provided by the University of Helsinki. Additionally, students completed a game project during those 8 weeks. After the setup of teams in the second week, teams held weekly scrum meetings, and they were required to use kanban (Trello) for task management.

The Application Development Methods module in the second year consisted of a mix of Finnish and international software engineering students. As the name implies, the module concentrated on software project management skills. The lectures covered some conventional project management, a number of development tools, and user-centered design. The technical skills included setting up a Java server, creating a responsive client-side, using GitHub and REST API, and usability testing tools. Other methods that the students were already familiar with included Trello and scrum meetings. Additionally, students used a variety of free online tools that they chose themselves. The composition of teams was constrained in a way that single-nationality teams were not allowed. Diverse teams tend to be more creative, and on the other hand, multicultural teams offer important skills for the future of international students.

The Software Business Start-up module was conducted in the beginning of the third study year. The idea of the module was to practice business skills by creating a mock start-up and developing a product prototype. The module built on the skills that had been acquired earlier including Git version control, weekly scrum meetings, voluntary use of kanban and other agile tools. Some new technical skills were introduced, namely the so-called MEAN stack that contains node.js and noSQL databases. Student teams were allowed to assemble freely, but the team size was limited to four. Very obviously, student ability to tolerate uncertainty had increased from one module to the next. In the second implementation, creativity and innovation were practiced during 1 week using the Google Ventures sprint model. The generation and development of product ideas was unprecedented in the classroom.

Certain positive outcomes were obvious, such as high student satisfaction and good retention rate (Holvikivi et al. 2017). The change from large study groups, separate lectures and laboratories into smaller, tightly knit groups seemed to have been a decisive factor in improving the results in the first years. Belonging into a group and working in teams was a simple way to enhance commitment to studies and overall

feeling of belonging, for students from diverse backgrounds in particular.

Nevertheless, the results of this case extend beyond agile courses, as agile work has been expanded to the entire curriculum. Not only the subject of study but also the methods of teachers in course design and implementation have applied agile ideas. The modules were not defined in much detail in advance; instead, the planning was flexible and done in small increments during the implementation. In particular, in case of heterogeneous student groups, this allowed more freedom in the realization.

Conclusion

As understanding the development process becomes more important for software developers, skills that help to master the process have to be included in software engineering curricula. New ways of teaching bring advantages to the institutions in terms of graduations and good results for courses as well, and enrich the work of faculty. Agile development is an exciting new avenue, which is not only embraced by the software industry but also applied to project work in other areas of business.

Algorithmic Thinking in Primary Schools

Joanne Blannin and Duncan Symons
Melbourne Graduate School of Education, The University of Melbourne, Carlton, VIC, Australia

Technological advances have changed the ways we work, learn, and play. For today's students to take full advantage of the opportunities these technologies afford, a set of ways of thinking, that mirror how computers function, are increasingly pervasive in schools. These include a thinking skill called algorithmic thinking that can be seen to be comprised of four key areas:

- Design thinking
- Decomposition
- Pattern recognition
- Abstraction

These four skills are used in schools to engage learners in problem-solving, critical thinking, and collaboration. They offer opportunities for learning across the curriculum. Algorithmic thinking activities can be seen in written maths problems, in historical research, in text analysis, and in the evaluation of art products. Current research suggests that engaging students in algorithmic thinking in their early schooling can open doors for them as adults entering the workplace (Deloitte Access Economics 2017).

As technological change continues to infiltrate our homes and schools, it has become clear that school curricula documents must reflect the society in which they are used. Curriculum writers are therefore seeking to engage students in the key thinking and practical skills that might enable their full engagement in the world of work and life beyond schools.

What Is Algorithmic Thinking and Where Did It Come From?

With its origins in mathematics, algorithmic thinking refers to logical, sequenced processes

that together create a desired outcome. Algorithmic thinking, in relation to technologies, has developed concurrently with computer programming and the microprocessor. At its simplest level, algorithmic thinking can be seen as $2 + 2 = 4$.

Although sometimes used interchangeably with the term computational thinking, algorithmic thinking is focused more on the design stage of problem-solving. Whereas, “In computational thinking, the focus is on the data and the interpretation of the data, and the algorithms are just tools available to help with that” (Gas Station Without Pumps 2010).

Algorithms, of the type discussed here, first came to the fore with computer programming breakthroughs of the 1940s. Indeed, algorithmic, mathematical, thinking can be seen to exist in the code-cracking histories of World War Two and Turing’s Enigma decryption machine.

A computer algorithm is a set of instructions that interact in a sequence to produce a desired outcome. An example is the “home” button on a mobile tablet or smartphone. When this button is clicked, it triggers a set of algorithms to complete the task, in this case, to display the home page on a device’s screen. Understanding that logic and sequencing underpin technology, and that errors or challenges with technology might be solved through a logical sequenced approach, are skills needed in a wide range of industries.

In Israel, England, the USA, and France, algorithmic thinking is already part of many school curricula documents (Deloitte Access Economics 2017).

In Israel, algorithmic thinking is presented as a core skill for successful twenty-first century life; in England, these skills are embedded with a curriculum focused on coding and computer programming.

No longer seen to be a skill unique to computer programmers, algorithmic thinking has become a new type of language and literacy in today’s world. Solving a problem using digital resources and designing logical models for implementing solutions are important skills for

today’s students. While a number of definitions of algorithmic thinking are available, there are four main aspects that appear common. These are explored below.

Abstraction

This aspect of algorithmic thinking focuses on making meaning from data. Students create rules about the data they have uncovered and view the broader implications of it. This might be understanding how data fits into a larger context or to reduce a complex idea to its fundamental concepts.

Systems Thinking

Many aspects of problem-solving and computing require an ability to see the complexity of the systems within which they are embedded. Systems thinking seek to understand the interactions of people, places, objects, or ideas within a system. In a school setting, this might be exploring how predators and prey interact and impact on each other within a microcosm.

Pattern Recognition

Beginning from an early age, students are often asked to engage with pattern-making and identification. With changing demands in the workplace, these patterning skills have increased in significance. Computer programmers use patterns to simplify and replicate basic commands. Students develop patterning skills to make sense of data and to identify inconsistencies from a high-level perspective. Making and exploring patterns can help students to make sense of large sets of data and can reinforce ideas of abstraction.

Decomposition

Sometimes called “factoring,” these skills see students break large sets of data or problems into their composite parts. This connects with the ideas of systems thinking as students compartmentalize problems in order to make better sense of possible solutions. When students are able to break large problems into smaller parts, they can more easily understand the nature of complex problems or ideas.

Changing Workforce Demands

Today's workforce is increasingly engaging with digital technologies, whether that is through email, digital databases or more recently, with virtual or augmented reality. The concept of work itself is also changing with one in three US workers now identifying as a freelance worker (Weber 2014) and one in four hoping to secure new employment in the next year just to "do something different" (Weber 2014).

These should be seen as opportunities for engaging students in new and innovative learning practices, after all, today's primary school students will enter the workforce in the 2020s and 2030s. It is likely that the workforce will be even more digitally, virtual and globally focused than it is already.

With scope for such large changes, it should be asked how teachers can possibly prepare students. If we do not know what social and global changes might occur, how can we teach students to engage with them? This is a question that has been raised by educational leaders and organizations globally.

One answer has come to the fore: prepare students not to use today's technologies but instead to learn how to learn. Developing the skills to learn is seen to be a way to future-proof the learning of students, who are hoped to leave schooling with transferable and flexible skills that may support them in their adult lives.

This focus on the future needs of students in the workforce has framed educational curricular such as the Australian Curriculum (Australian Curriculum Assessment Reporting Authority 2016), the National Curriculum for England (Government Digital Service, UK 2014), and the Israeli higher education program, Ghavim (2017).

New Curriculum Demands

The Australian Curriculum is the newest of these curricula and seeks to engage students in developing core computing skills from ages 5–16. Beginning in the early years of schooling, students are asked to identify patterns and exploring basic algorithms through step-by-step written

activities. These activities might include following or recording a recipe or creating treasure maps with instructions for others to follow.

The Australian Curriculum is designed to engage students in specific thinking skills. Problem-solving, creativity, and collaboration are core foci in the Australian Curriculum and by giving these areas greater prominence, there is an expectation that teachers will place a greater emphasis on helping students develop the so-called "21st century skills" in addition to content related to the various disciplinary areas. As students develop skills, they may begin to design and implement more complex algorithms that leverage technologies in reaching a solution.

Reinforcing the notion of the Australian curriculum as a thinking curriculum is the statement that up to 50% of the curriculum can be completed offline, without the use of computer technologies. Offline learning activities can be effectively used to reinforce algorithmic thinking and might include designing a board game for others to play, finding errors in a list of instructions, or identifying algorithms used in the real world.

With changing curriculum demands in a number of countries worldwide, it is important to restate that the aim of these documents is rarely to produce a generation of computer programmers. With increasing global challenges, such as climate change, unstable political environments, and catastrophic weather events, there is a growing need for individuals who can analyze, decompose, reflect on, and design solutions. The Australian Curriculum frames this interpretation of curriculum in saying, "The curriculum is designed so that students will develop and use increasingly sophisticated computational thinking skills, and processes, techniques and digital systems to create solutions to address specific problems, opportunities or needs" (Australian Curriculum Assessment Reporting Authority 2016).

This curriculum positions the skills that it seeks to develop in students as "... develop[ing] and employ[in] strategies for understanding and solving problems in ways that leverage the power of technological methods to develop and test

solutions (Australian Curriculum Assessment Reporting Authority 2016).”

It is pertinent to note that many teachers already engage students in developing these skills in classrooms around the world. These teaching strategies are sometimes called inquiry learning, activity-based learning, or problem-based learning. However, today’s curriculum demands ask teachers to make visible the affordances of technologies in solving complex, open-ended problems. Teachers are now asked to highlight the specific thinking skills that students are using and seek to engage them in reporting on their learning strategies as they solve problems.

Previously, teachers might have asked students to create a paper graph to record the passing traffic outside the school, and then analyze the data to inform an appeal to the local roads authority. New curricular demands would see students making informed choices about which resources and technologies they might use to record passing traffic. These might include developing an app to record traffic that students could use on computer tablets, as they left school each day, or mounting a camera by the school gate that has been programmed to take photographs at designated intervals.

Students might then use the algorithmic thinking skills of abstraction, decomposition, and systems thinking to make an informed case for solving the problem of increased traffic at certain times of day. They might implement, then review, their solution and use pattern recognition strategies to interpret the data they gather.

Although, in these two examples, students are working to solve a similar problem, it is clear that the development of algorithmic thinking skills separates the learning experiences. With a focus on visible and strategic thinking skills, students can engage in more complex, collaborative, and real-world problem-solving.

Beginning to Think Algorithmically

There are a number of online resources available to engage with algorithmic thinking skills. A number of these focus on the development of

computer coding skills. Coding, or programming, can be seen as the newest component of curriculum documents. These skills, therefore, represent the most novel aspects of the curriculum for teachers and learners, and are often promoted as an entry point for beginner learners.

An online search will provide a range of beginners’ guides to computer coding that will introduce concepts of algorithmic thinking. An American not-for-profit organization, called Hour of Code (<https://hourofcode.com>), is one of the most popular and prominent websites for beginners in this area. The Hour of Code website provides free narrated, video courses in basic coding, that walk the learner through developing and implementing computer programs using a “drag and drop” interface. As this suggests, the learner drags coding “blocks” across the screen. By connecting blocks together, a computer code is developed that can then be “run” to complete a basic task. An example might be designing a snowflake by dragging a sequence of codes together that use forwards, backwards, left, and right “blocks.” When the learner clicks on “run,” the code is executed and any problems or errors are revealed.

Drag and drop coding is used in a range of softwares that are freely available as online, web-based resources and as smart device apps.

Algorithmic thinking invites learners to engage in deep thinking, in rationale, sequential processes, and in solution-testing and review. Learners who develop these skills may have increased opportunities in a wide range of career fields beyond school.

Global Educational Changes

There has been a steep increase in the language of computing and computers since the year 2000. Words such as Blog, Wiki, Upload, Download, Coding, and Apps have become part of the common language of society. This is true, too, in schools where computer vocabulary continues to grow as technology changes. These swift language developments can be seen to be indicative of the pace of change in the world and the classroom.

Many teachers around the world now work in Internet-connected classrooms and schools. These teachers can now engage with students online, to support and grow their learning, use interactive resources and virtual reality to bring the world into the classroom and even solve real problems with digital solutions.

As governments around the world seek to align their curricula to shifting needs of their societies, the significance of a set of skills called “algorithmic thinking” increases. It is of note, however, these documents do not seek to develop a generation of computer programmers.

While this shift in curriculum focus can be seen to be driven by society at large, there is no expectation that every child should become a computer technician, programmer, or developer. In fact, the inclusion of algorithmic thinking in schools seeks to broaden student’s opportunities, not narrow them.

Understanding the skills of algorithmic thinking, drawing on its background in mathematics and the first computers, provides insight into how digital technologies work.

This is then can create endless possibilities for innovative, perhaps entrepreneurial, skills to be developed. The 21st century skills provide unique learning experiences that teach students how to

learn in the ever-changing technology-enhanced world they will enter after school.

Take the example of a group of 10-year-old students in a rural primary school in Australia (Table 1). These students are aware of a problem in their wider community: ridesharing services are difficult to arrange and access, meaning a number of students each day are unable to get to school.

These students worked through the four aspects of algorithmic thinking to better understand the challenges of solving the problem. The table above shares the thinking of the students as they moved towards a solution.

Working through this process has helped the students develop a proposed solution: a giant map of the routes parents drive to get to school. These students might need to further investigate the problem. How can a giant map at school help them when they are at home? How could they make the map reflect last minute changes to driving routes, due to weather, cattle, accidents, and so on?

This could lead students to develop a GPS tracking app that parents could use as they drive school. This would not only go towards solving the problem but would also provide ongoing algorithmic thinking opportunities as they develop, trial, review, and maintain their new ridesharing system.

Algorithmic Thinking in Primary Schools, Table 1 Components of algorithmic thinking

Aspect of AT	Key questions	Students’ responses
Design thinking	What is happening here? Why is ridesharing hard to arrange? Which part of the “system” (in this case, the arranging of ridesharing) is causing the problem? How does each part inform the other?	We don’t always know who needs a ride When parents are unavailable at the last minute, we don’t know who could offer a ride We live far away and we could get a ride to the main road, but we don’t know when people are driving past
Decomposition	Where are the main points of challenge? Which parts work well?	Contacting people driving past is difficult. Last minute changes are hard. There are people to drive us – but we can’t always find them!
Pattern recognition	What patterns might help you solve this problem? What do you need to know?	We need to know the routes that people drive so we can find a lift to school We could ask people to map their routes to school and share it with us
Abstraction	How can we summarize the data? What should we look for in the data? How can this data help us solve the problem?	We need to collate all the maps onto one big map so we can see where people drive and whether we can find a lift to school

Using Algorithmic Thinking to Solve Problems in Primary Schools

This section presents examples of algorithmic thinking in action. These examples are framed as learning activities across the three main stages of primary schooling: early years, middle years, and senior years. Students are supported to develop increasingly complex algorithmic thinking skills as they progress through primary school. These critical skills are seen to be imperative for all students from the beginning of their schooling, "... it is vital that we start with algorithmic thinking early on, and help the students advance towards, ultimately, mastery of the subject" (Hromkovic et al. 2017).

With this mandate for all students to learn algorithmic thinking skills, the following examples make use of both digital technologies and more traditional, off-line resources. This reflects the interpretation of algorithmic thinking as a thinking skill, not only a computer or online skill.

Algorithmic Thinking in the Early Years

In the early years, students are supported to understand sequenced events, patterns, and designing solutions. At this level, this might include drawing, discussing, and/or shared writing, rather than formal, written responses. An example is a group of 5-year-old children who are planning for a school excursion. The teacher explains that they will need to pack a picnic for the class to enjoy. As a class, the students make a list of possible foods and drinks they might like to include.

From here, the teacher points out that there is a wide variety of possible sandwich fillings and asks how can we determine all the options so we know what we need to buy? In small groups, students draw ways to represent all the possible sandwich filling combinations and are then led to identify patterns between the groups' drawings. There are a few ingredients that appear to be consistent across the groups: bread, butter, and Vegemite. Each group is asked to redesign their drawing to make this pattern clear. Some draw a giant loaf of bread, others add the word "bread" to each of the

sandwich options they chose. The teacher comments that by looking for patterns they have made useful additions to their drawings. You cannot make a sandwich without bread, but we may not have realized this, if we had not searched for patterns in our data.

The teacher next asks the students to consider how they might best create one drawing or diagram to represent all the options in the class. Again, in small groups, students are supported to design a flow chart that leads students through the sandwich filling options. The flow charts are then combined into a single class flow chart, again highlighting patterns that have emerged, and this is followed by a discussion of the processes and problems they worked through to create the final flow chart.

The teacher highlights the use of patterns to simplify the initial drawings and the role of abstraction in ensuring that they all focused on sandwiches, rather than just on fillings. While the language of algorithmic thinking is likely beyond student's comprehension at this stage, they have begun to develop concepts of patterning and algorithms as tools for problem-solving.

Algorithmic Thinking in the Middle Years

As students approach the middle years of primary schooling, they begin to engage with algorithmic thinking across a wider range of curriculum areas. This might be in an interdisciplinary project or through one specific learning area. This example engages students in geography learning (human land use) and algorithmic thinking strategies.

A class of 10-year-old students is seeking to understand why some areas of the playground are busier than others, as the footy game played at lunchtimes appears to be impacting on those who wish to engage in quiet play activities.

To begin, students have explored the geology of their school grounds and have collected a range of measurements. These include the height above sea level of five locations in the school grounds, the number of students in these five locations at recess times, and the types of play that occur in

each location. The teacher sees an opportunity to engage students in complex problem-solving using algorithmic thinking strategies, namely pattern recognition and decomposition.

The teacher guides students to begin categorizing their data. Students create categories of quiet play, sports games, and noisy, running games. Each student group adds their data to these categories and the teacher leads a discussion about the patterns they identify. She leads the students to make broader, abstracted comments on each category, such as more “people play noisy running games at location three.” She then asks them to assign the locations and height above sea level to each activity in the three categories.

As students complete this task using a Digital Media Board, they begin to reorganize and rename their findings to better fit the categories. Some students make comments about the relationship between height above sea level and the types of play that students undertake.

The teacher uses this comment to introduce ideas of decomposition. They break the data into parts and focus on the data from one location, for one activity. They realize that this data was gathered on a slight hill and is the highest point in the school grounds. The activities at the location are reported as mainly “quiet play.”

Students use this example to generate the hypothesis that higher locations in the school grounds are better for quiet play. The groups then return to their data to validate their findings. They use the Digital Media Board to share their ideas and findings with the class and to generate a whole-class conclusion.

Their findings suggest that if sports play was limited to two main locations in the school grounds, there would be more space for noisy, running games, that would, in turn, and using systems thinking, increase the space for quiet play.

Students are led to discuss the use of pattern recognition and decomposition in understanding the complexity of the problem. Initially, students believed the footy game impacted on the quiet play areas, but their findings suggest that it was

in fact the noisy, running games that were impacted by the footy players, who in turn impacted on the quiet play areas.

Algorithmic Thinking in the Senior Years

In the final years of primary schooling, students are supported to engage with technologies, computer coding, and solution design. In this example, a group of 12-year-old students are engaged in a STEM learning project focused on the exploration of Mars.

The teacher begins by providing a scenario whereby it is some time in the future and Earth’s resources are running low, we are broadly overpopulated, and climate change is regularly resulting in catastrophic disasters. As one way of dealing with these issues, the global community has sent humans to Mars in the hope of colonizing the planet and making human habitation possible.

As the students and the teachers begin to work through this scenario, they move through each of the STEM disciplines. In the area of science, they must consider general requirements for the sustenance of life. Thus, how will food, water, shelter, and breathable air be provided. Quite quickly they may realize that they will need to grow plants. Not only will they provide a source of food but through photosynthesis oxygen will also be released.

Students will design the base station for the Mars settlement. This will draw on digital technologies, engineering, and mathematics. They will plan for how the inhabitants of the base station will move from location to location around the settlement. Imagining that a codable robot (for example, Sphero or Dash bot) is a Mars rover controlled remotely from the base station. This will be achieved by using grid references (or Cartesian coordinates for more advanced learners) and drag and drop coding. The input device for the code would usually be a Bluetooth enabled android or iOS tablet or smartphone. It is suggested that a large-scale map of Mars is created on the floor of the classroom. A number of landmarks or significant areas of interest are included

on the map (for example Olympus Mons, the largest volcano in our solar system and Valles Marineris, a valley larger than the Grand Canyon on Earth). Students should draw on their developing understanding of abstraction, systems thinking, pattern recognition, and decomposition to plan and have the rover navigate its way around a preplanned circuit.

We suggest the teacher identify the component parts of algorithmic thinking and create formative assessment matrices to provide feedback to students about their progress and areas for future growth.

Summary

Algorithmic thinking can be seen as encompassing a range of skills including the four areas of design thinking, decomposition, pattern recognition, and abstraction. In this entry, we have described and explored several activities that can help students to develop algorithmic thinking in the early, middle, and senior primary school levels.

In the early years, through planning a picnic, students could develop an understanding of basic algorithms represented through drawings. In the middle years, students might generate, record, and analyze data related to playground usage. The context of Mars exploration, in the upper primary years, connects students' learning to ongoing media reports and represents an interdisciplinary and engaging approach to algorithmic thinking within STEM learning.

This entry presents algorithmic thinking as an essential and strategic focus area for primary school learning as we continue to see the demand for these technological skills increase in the workplace.

Android apps-based learning approach; Firewall; Information security education; Security hands-on labs

Introduction

As mobile devices grow increasingly in popularity within the student community, novel educational activities and tools, as well as learning approaches, can be developed to get benefit from this prevalence of mobile devices (e.g., mobility and closeness to students' daily lives). Particularly, information security education should reflect the current trend in computing platforms away from the desktop and toward mobile devices.

Nowadays, the need to use a practice- and application-oriented approach in information security education is paramount (Chen and Lin 2007). Hands-on learning through lab exercises plays a key role in information security education. In fact, a security education curriculum that does not give the students the opportunity to experiment in practice with security techniques cannot prepare them to be able to protect efficiently the confidentiality, integrity, and availability of computer systems and assets. In addition, rather than only teaching abstract concepts and assigning abstract exercises, courses that also engage students in real-world settings will promote effective information security education (EDUCAUSE 2014; Loveland 2011).

Hands-on lab exercises on various information security topics have focus primarily on desktop environments, whether physical or virtual, and consequently can be implemented only inside

isolated laboratories environments (Whitman et al. 2014; Trabelsi et al. 2013; Trabelsi and Alketbi 2013; Trabelsi 2011; Vigna 2003a, b; Yuan and Zhong 2008; Caltagirone et al. 2006; Hill et al. 2001; and Trabelsi and Mustafa 2014). Recently, the computing landscape, however, is shifting. The dominant computing platform is becoming the mobile device (Andrus and Nieh 2012). Nevertheless, the real-world constraints and operating environment of mobile devices are quite different from traditional desktop-based laboratory environment. Therefore, it is important for students to learn in this new environment whose prevalence and popularity can be used to create new hands-on lab exercises and tools for information security education (Andrus and Nieh 2012).

In fact, over the last decade, the use of mobile devices for both personal and business purposes has exploded. The arrival of smart mobile devices (Google-Android-based smartphones and tablets) and the booming of mobile applications (known as apps) in recent years have only accelerated this trend (Bhattacharya et al. 2014). Mobile devices have been consequently turned into powerful general-purpose computing platforms. More and more users and businesses use mobile devices for processing personal, financial, and commercial data or use them to organize their work and private life. Particularly, in the academia environment, more and more students are using mobile devices for both personal and academic reasons (Levine and Kossuth 2011). Hence, an enormous array of mobile devices is making its way to college campuses. As smart mobile devices grow increasingly in popularity within the student community, novel educational activities and tools, as well as learning approaches, can be developed to get benefit from this prevalence of mobile devices (e.g., mobility and closeness to students' daily lives). Hence, the teaching of information security concepts should reflect the current trend in computing platforms away from the desktop and toward mobile devices.

As the need to use a hands-on-based learning approach in information security education is paramount, and as mobile platforms grow increasingly in popularity within the students' community, learning approaches that aim at taking

advantages of the benefits of mobile devices and the best practices in learning information security should be explored. The approaches should aim to promote students' interests and increase their self-efficacy. In this work, a learning approach that offers two Android apps for the students to further learn the intricacies of network traffic filtering and enhance their hands-on skills on firewall filtering rules implementation is presented. The apps allows students to further practice network traffic filtering outside the traditional isolated laboratory environment, in the real-world environment, i.e., anywhere and anytime, at the students' convenience. The two Android apps are a firewall app and a network packet generator app, called Advanced Firewall and Packet Generator, respectively. Based on statistics from Google Play Store, in September 2019, the Packet Generator app has been rated 4.0 with over 500,000 downloads worldwide. As a consequence, in addition to the traditional inside laboratory activities which are limited by the time allocated and often do not reflect the real-world settings, students will be able to continue practicing further network packet filtering using their mobile devices in the real-world environment, at their convenience. The impact of the two Android apps on the students' performance in terms of achieving the course outcomes is also discussed.

Efficient Learning Approach

The importance of hands-on learning has long been recognized in the learning theory literature (Du et al. 2010). In traditional information security programs, students are expected to be heavily involved in hands-on lab activities. Therefore, the first characteristic of an efficient learning approach is its hands-on-based learning that couples security policies analysis with protection solution practices. In practice, this consists into implementing and testing the appropriate firewall filtering rules for specific security policies, on Android mobile devices.

The second characteristic of an efficient learning approach is its real-world relevant learning. The mobile device itself is becoming more

relevant than other existing learning platforms to real-world applications. As a consequence and in addition to the inside laboratory activities, students are encouraged to test and debug firewall filtering rules in the real-world environment, using mobile devices.

Thirdly, Android platform has been chosen over iOS platform to develop the proposed educational apps for several reasons. First, Android is the fastest-growing mobile platform (Andrus and Nieh 2012; Guo et al. 2013) to date, and its popularity makes it of tremendous interest to students. Second, Android platform is open-sourced, while Apple iOS platform has license restrictions. Moreover, since Android is based on the open-source Linux kernel, students can leverage a wealth of Linux tools and documentation. That is, Android allows exploration of a complete production system including the OS kernel, user space libraries, and a graphical user environment written in Java. Third, as a commercial platform, Android continues to be developed and improved which naturally evolves the platform as a pedagogical tool, enabling students to learn in a modern context.

Hands-on Learning Activities on Firewalls

A pedagogical model to teach firewalls concepts consists usually of two main phases. In the first phase, and during the hands-on lab activities, the instructor asks the students to discuss and analyze a set of security policies related to a variety of network traffic scenarios. Then, the instructor asks students to write the appropriate filtering rules for each security policy. Students are then instructed to implement and test filtering rules using classical firewall devices and wired or wireless local area networks.

In the second phase, students are then instructed on how to implement and test their firewall filtering rules on their mobile devices, using step-by-step tutorials. In fact, in addition to the inside laboratory activities, students are requested to test and debug firewall filtering rules in the real-world environment, using mobile

devices. This will help students to obtain an instant gratification and confidence from the hands-on practice and encourage them to create specific filtering rules to filter real-world network traffic. This also has the additional benefits of not only facilitating students to learn network traffic filtering skills but also heightening their awareness and understanding of firewall concepts in the real-world environment.

Design Considerations

Firewalls control the access into and from networks and computers based on a set of filtering rules, which reflect and enforce the organization's security policy. It is the firewall's job to make filtering decision on every packet that crosses it: either to let it pass or to drop it.

Firewall and network packet filtering is considered an important topic for a course on network security. There are basic network packet filtering topics that should be taught when offering a security course on firewalls, namely, basic network packet filtering, common standard services filtering, and nonstandard services filtering. There are also advanced network packet filtering topics, such as stateful firewall packet filtering using TCP flags, and packet deep inspection (DPI), also known as packet content inspection, and consistency verification of the filtering rules.

Ideally, when designing and implementing an educational firewall application, the above basic and advanced topics should be taken into consideration to help students improving their hands-on security skills on firewall configuration and network packet filtering. In addition, the educational firewall application should offer a user-friendly GUI interface to allow students easily create and manipulate filtering rules, including updating the values of the filtering rule's fields and the order of the filtering rules. Students should also use means to test and debug the implemented filtering rules and should be immersed in a real-world relevant learning environment, by taking advantage of the benefits of mobile devices.

Android-Based Mobile Apps for Hands-On Education, Fig. 1 Apps of the Android learning approach

Android Apps

The discussed learning approach uses the two Android-based apps: Advanced Firewall and Packet Generator apps (Fig. 1). Advanced Firewall app allows implementing filtering rules and/or selecting rules from a set of predefined rules to filter a diversity of network traffic types and Internet services. Packet Generator app is used to generate specific network traffic to test the efficiency of the implemented filtering rules relative to the outgoing and incoming network traffic. The use of both apps allows students to practice implementation, testing, and debugging of firewall filtering rules, while they are outside the isolated laboratory environment. Hence, in addition to the inside laboratory activities, students will get further chances to improve their hands-on security skills on firewall concepts, using their Android mobile devices. The following subsections describe the two apps.

Advanced Firewall App

Advanced Firewall app offers a set of basic firewall functions that allow performing the following:

- Implement basic filtering rules to filter TCP and UDP network traffic. The filtering rules are defined by setting the values of the source/destination IP addresses and the source/destination ports.
- Implement basic filtering rules to filter ICMP network traffic. The filtering rules are defined by setting the values of the source/destination IP addresses and the ICMP Type/Code fields.

- Select rules from a list of predefined rules to filter standard Internet services, such as Web, Email (SMTP/POP3), and FTP.
- Implement filtering rules to filter nonstandard TCP and UDP services.
- View the logs data of filtered network packets.

A future version of Advanced Firewall app can be enhanced to include more educational firewall functions to cover advanced topics, such as stateful firewall packet filtering using TCP flags, application gateway firewalls (Proxy), and Virtual Private Networks (VPN). The following subsections describe in details the current main basic security functions of Advanced Firewall app.

Basic Packet Filtering

Basic firewall packet filtering is the selective passing or blocking of packets as they pass through a network interface. The most often used criteria that packet filtering use when inspecting packets are source and destination IP addresses, source and destination TCP/UDP ports, and type and code fields in an ICMP header (Northcutt et al. 2005). Firewall users need to have basic knowledge about TCP/IP protocols and Internet services in order to be able to create the appropriate rules for filtering specific network traffic.

Predefined Filtering Rules for Standard Internet Services

Standard Internet services run usually on standard ports. Standard ports range is in the interval of 1 to

1023. For example, the standard ports for Web (HTTP) and FTP services are 80 and 21, respectively. Firewalls include usually predefined rules to filter standard services. Firewall users can select rules from the list of offered predefined rules to filter network traffic relative to Internet services. However, in contrast to writing basic filtering rules, firewall users need simply to have general knowledge about Internet services, to be able to select the appropriate predefined filtering rule for each specific Internet service.

Nonstandard Services Filtering

Nonstandard services run on nonstandard ports. Nonstandard port numbers are usually larger than 1023. Firewalls are unable to filter nonstandard services unless the user provides the firewall with the TCP or UDP ports of the nonstandard services to be filtered. In practice, this is achieved by creating a new service profile for the nonstandard service, and by specifying its corresponding TCP or UDP port number.

App's Implementation

Advanced Firewall app is written in Java language using Eclipse IDE. The main GUI interface of Advanced Firewall app allows the mobile device's users to select the source of the network traffic (incoming or outgoing) to be filtered or to view the log data relative to the previously filtered packets, as shown in Fig. 2.

To filter network traffic, the user can either select filtering rules, from a set of predefined

Android-Based Mobile Apps for Hands-On Education, Fig. 2 Main user interface of Advanced Firewall app

Android-Based Mobile Apps for Hands-On Education, Fig. 3 List of predefined filtering rules offered by Advanced Firewall app

Android-Based Mobile Apps for Hands-On Education, Fig. 4 List of selected and user-created filtering rules

filtering rules, or create new filtering rules. Figure 3 shows the list of predefined rules offered by Advanced Firewall app for filtering Ping traffic and Web/FTP/DNS/Email/Telnet services.

As an example, Fig. 4 shows a list of selected predefined and user-created filtering rules.

Packet Generator App

The discussed learning platform also uses a network packet generator app, named Packet Generator, for generating specific network traffic to test the efficiency and correctness of the implemented filtering rules in mobile devices. In fact, the objective behind developing this app is to allow a single student to conduct, from a mobile device, self-testing of his implemented filtering rules for the outgoing network traffic. However, to test the filtering rules for the incoming network traffic, Packet Generator app should be installed into another mobile

device from which the network test traffic can be generated. Packet Generator app can be used also to test the resilience of target hosts against denial of service (DoS) attacks traffic (Trabelsi et al. 2013), by generating network flood traffic at a high rate.

Implementation of the App

Packet Generator app is written in Java language using Eclipse IDE. The application is freely downloadable from Google Play Store (<https://play.google.com/>). Based on statistics from the Google Play Store, and as per September 2019, Packet Generator app turned popular with over 500,000 downloads worldwide and a 4.00 users' rating.

Using a friendly GUI interface, the app allows Android mobile device's users to specify the type of the network traffic to be generated (i.e., TCP, UDP, or ICMP). Practically, for TCP and UDP

network traffic, the app offers the user the options to specify the IP address of a target host and a random or specific TCP or UDP port number. For ICMP network traffic, the app offers the user the options to specify the IP address of a target host and the ICMP Type and Code field values.

For any network traffic type, the user can choose the rate of traffic to be generated (i.e., number of packets per second) and whether or not the desired traffic will be sent continuously. In addition, for ICMP traffic, the user can select to flood the target host. In this case, the flooding traffic is sent at the highest possible rate that the mobile device can support. In general, flooding option in Packet Generator app allows testing the resilience of target hosts against DoS attack traffic.

DoS Attacks Generation Using Packet Generator App

DoS attacks topic is considered as one of the major topics for courses on network security, especially for courses that are concerned with intrusion and malicious network activities detection and prevention. Commonly, a DoS attack attempts to render a system unusable or significantly slows down the system for legitimate users by overloading the resources so no one else can access it. A DoS attack may target a user, to prevent him from making outgoing connections on the network. A DoS attack may also target an entire organization, to either prevent outgoing traffic or to prevent incoming traffic to certain network services, such as the organization web page.

DoS attacks are much easier to accomplish than remotely gaining administrative access to a target system. Because of this, DoS attacks have become very common on the Internet. Most DoS attacks rely upon weaknesses in the TCP/IP protocols. For example, a SYN flood DoS attack occurs when a host becomes so overwhelmed by SYN packets initiating incomplete connection requests that it can no longer process legitimate connection requests.

In information security education, hands-on lab exercises on DoS attacks allow usually

Android-Based Mobile Apps for Hands-On Education, Fig. 5 TCP packets generation example

students to learn DoS attack traffic generation and implement the corresponding defensive solutions. Practically, students can use network packet generator tools to generate DoS attack traffic. However, it is not recommended to use DoS tools developed by hackers or untrusted sources, since the tools may carry virus and malicious codes.

The following screenshots are examples on how to use Packet Generator app to generate a diversity of common DoS attacks.

Figure 5 shows how to generate continuously TCP packets targeting port 80 in a host with IP address 192.168.1.1, at the rate of 3000 packets per second.

Figure 6 shows how to generate 1000 UDP packets in 1 s, targeting random ports in a host with IP address 192.168.1.1.

Figure 7 shows how to flood a target host with IP address 192.168.1.1 with ICMP packets, using the highest traffic rate that the mobile device can generate.

Android-Based Mobile Apps for Hands-On Education, Fig. 6 UDP packets generation example

Android-Based Mobile Apps for Hands-On Education, Fig. 7 ICMP flooding traffic generation

Related Android Firewall Apps

The development of Android firewall apps is not a new idea by itself as there are many Android apps acting as firewalls. In Google Play Store, many Android firewall apps have been identified, namely, *DroidWall*, *Android firewall*, *Root firewall*, *Mobiwol firewall*, *Firewall builder*, *Honeybadger firewall*, *Traffic firewall*, *Firewall plus*, *IP spoofing detector and firewall*, *NoRoot Firewall*, *AFWall+*, *Firewall Gold*, and *LostNet NoRoot Firewall*. Table 1 summarizes the firewall features of these Android apps, particularly their abilities to allow users to easily and freely implement and manipulate firewall filtering rules, as well as their limitations and strengths. In addition, Table 1 compares these apps with the proposed Advanced Firewall app.

The analysis results of these apps conclude that they have been designed almost without educational objectives and offer limited firewall functions to create and manipulate filtering rules.

Moreover, the use of some apps is complex and often requires advanced knowledge of networking concepts and protocols. For example, *Android firewall* and *Firewall builder* allow the user to enter his/her custom filtering rules in script syntax. Also, the GUI interfaces of some apps do not allow friendly view of the implemented filtering rules. There are many apps that do not allow viewing the log data of the filtered network packets, such as *DroidWall*, *Android firewall*, *Root firewall*, *Firewall builder*, *Traffic firewall*, *Firewall plus*, *IP spoofing detector and firewall*, *Firewall Gold*, and *LostNet NoRoot Firewall*.

Other apps do not allow free manipulation of the fields of the filtering rules. For example, in the case of filtering TCP and UDP packets, many apps do not allow setting the source and destination IP addresses and/or the source and destination ports (*DroidWall*, *Android firewall*, *Root firewall*, *Mobiwol firewall*, *Traffic firewall*, *Firewall plus*, *IP spoofing detector and firewall*, *AFWall+*, *Firewall Gold*, *LostNet NoRoot Firewall*). In case of

Android-Based Mobile Apps for Hands-On Education, Table 1 Related Android firewall apps’ features

Firewall features	Apps supporting this feature	Advanced Firewall (Our Firewall App)
Offer easy-to-use GUI interface	[DroidWall, Android firewall, Root firewall, Mobiwal firewall, Honeybadger firewall, Traffic firewall, Firewall plus, IP spoofing detector, NoRoot firewall, AFWall+, Firewall Gold, LostNet NoRoot firewall]	✓
Filter TCP and UDP traffic based on IP address	[Firewall builder, Honeybadger Firewall, NoRoot firewall]	✓
Filter TCP and UDP traffic based on port number	[Firewall builder, NoRoot firewall]	✓
View log data of dropped packets	[Mobiwal firewall, Honeybadger firewall, NoRoot firewall, AFWall+]	✓
Filter ICMP traffic based on the Type and Code fields’ values	None	✓
Allow selecting predefined filtering rules for specific services and applications	[Firewall builder]	✓
Filter Web traffic based on URL address	[Honeybadger firewall, IP spoofing detector]	✓
Filter nonstandard services	[DroidWall, Android firewall, Root firewall, Mobiwal firewall, Honeybadger firewall, Traffic firewall, Firewall plus]	✓
Filter both incoming and outgoing traffic	[Firewall builder, Honeybadger firewall, NoRoot firewall]	✓

filtering ICMP traffic, all investigated Android firewall apps do not allow to set the ICMP Type and Code fields.

On the other hand, most investigated apps focus on controlling solely the other apps installed in the mobile device that require accessing Internet. That is, the users can solely allow or deny the installed apps to access the Internet. *DroidWall*, *Root Firewall*, and *Mobiwal* apps are examples of such apps.

In contrast, Advanced Firewall app has been designed mainly for educational purpose and offers a more user-friendly GUI interface to implement and manipulate firewall filtering rules. Furthermore, Advanced Firewall app offers a more comprehensive set of educational firewall functions that are appropriate and useful for information security education. Hence, compared to the investigated aforementioned Android firewall apps, Advanced Firewall app is more adequate for implementing educational hands-on lab exercises on firewall packet filtering, allows students to better anatomize firewall

concepts in real-world environment and outside laboratory activities, and consequently enhances further student’s firewall hands-on skills.

Assessment Process

Course learning outcomes achievement is assessed using a comprehensive assessment and evaluation system (Ibrahim et al. 2015). The assessment system consists of three main processes based on ABET guidelines (Sanderson 2009). At the lower level, the course assessment process is used to measure the achievement of course outcomes (COs). COs describe the knowledge, skills, and/or competencies that the students should have or be able to demonstrate upon completion of the course. COs assessment results are then combined with other program-level assessment tools (e.g., student survey, exit exams, exit interview, etc.) to measure the achievement of the student outcomes (SOs) at the next stage. SOs describe what students are expected to learn and

be able to do by the time of their graduation, which include cognitive, affective, behavioral, social, and ethical performances. At the third level, the program educational objectives (PEOs) are measured and evaluated. PEOs are broad statements that describe the strategic career and long-term professional accomplishments the program is preparing its graduates to achieve 3–5 years after graduation.

During the course offering, each instructor teaching the course is responsible for collating the assessment data for the taught section(s) and preparing a simplified section assessment report. The section assessment reports are then sent to the course coordinator. To minimize the assessment effort, the section assessment report includes only the following information:

1. The number of students
2. The assessment tools used
3. The mean and standard deviation for each outcome achievement level
4. Any assessment-related remark (optional)

Although bimodal distribution could be more appropriate in some situations to model the students' performance, the tool assumed a Normal distribution for the students' performance to facilitate the aggregation of the assessment data from different sections and different assessment instruments producing the overall CO assessment results. To calculate the mean and the standard deviation for each learning outcome, the course coordinator aggregates the performance of the students in each used assessment tool. Each course c has a set of outcomes O_c , a set of assessment tools T_c , and is offered to a set of sections S_c . Therefore, the mean and standard deviation for outcome o is calculated as follows:

$$\mu_{soc} = \frac{\sum_{t \in T_c} \mu_{tsoc} \times \alpha_{to}}{\sum_{t \in T_c} \alpha_{to}} \quad (1)$$

$$\sigma_{soc} = \sqrt{\frac{\sum_{t \in T_c} \sigma_{tsoc}^2 \times \alpha_{to}}{\sum_{t \in T_c} \alpha_{to}}} \quad (2)$$

where μ_{tsoc} and σ_{tsoc} are the mean and standard deviation when tool " t " is used in section " s " to assess outcome " o " of course " c ," α_{to} is a mapping factor that determines the contribution of the assessment tool t to the achievement of outcome o such that $\sum_{o \in O_c} \alpha_{to} \leq 1$.

The course coordinator compiles the received section assessment reports and calculates the aggregated course-level assessment results. Using the mean and standard deviation for measuring the achievement of the outcomes at the section level facilitates the aggregation of the results from different sections to calculate the overall course assessment, regardless of the assessment tool used in each section. For each outcome o of course c , the aggregated mean and standard deviation are calculated as follows:

$$\mu_{oc} = \frac{\sum_{s \in S_c} \mu_{soc} \times n_s}{\sum_{s \in S_c} n_s}, \quad (3)$$

$$\sigma_{oc} = \sqrt{\frac{\sum_{s \in S_c} \sigma_{soc}^2 \times n_s}{\sum_{s \in S_c} n_s}}, \quad (4)$$

where n_s is the number of students in section s . Assuming Normal distribution, the achievement level of outcome o of course c (noted A_{co} below) is calculated as the percentage of students who scored above a predefined cutoff threshold λ , as shown next:

$$A_{oc} = 0.5 - 0.5 \times \text{erf}\left(\frac{\lambda - \mu_{oc}}{\sigma_{oc} \times \sqrt{2}}\right). \quad (5)$$

For example, assume that $\mu_{co} = 0.74$, $\sigma_{co} = 0.093$, and $\lambda = 0.7$, the outcome achievement level in this case is the percentage of students whose score is above λ , which in this case is 66.64%.

Course Learning Outcomes Assessment

As a case study, the two discussed Android apps have been offered to students enrolled in a course called Network Border Control (SECB358)

Android-Based Mobile Apps for Hands-On Education, Table 2 Mapping the course outcomes to Bloom's taxonomy

Outcome	Level of Bloom's taxonomy
CO1: Describe TCP/IP protocols and network services	Analysis
CO2: Identify common security threats	Analysis
CO3: Configure personal firewalls, network firewalls, and VPNs	Synthesis
CO4: Implement firewall filtering rules for different network architectures and services	Synthesis
CO 5: Evaluate different types of network architectures	Evaluation

during several academic years. SECB358 is a course that is concerned mainly with network packet filtering, firewall, and VPN topics. A major topic taught in SECB358 course is firewall filtering rules implementation. The course also offers students an extensive set of hands-on lab exercises on these topics. SECB358 course has five learning outcomes, as shown in Table 2. Since SECB358 is an advanced course in information security, the outcomes have been selected carefully to reflect the top three levels in Bloom's taxonomy of cognitive domain (analysis, synthesis, and evaluation).

During the 2009/2010, 2010/2011, and 2011/2012 academic years, students enrolled in SECB358 course were not offered the two Android apps. Students had the opportunity to practice firewall packet filtering, only in the in-campus isolated labs environment. In addition, students are allowed to practice only for a limited time. However, starting from fall 2012, SECB358 course's committee decided to offer the two Android apps to allow students to further practice firewall packet filtering implementation outside the isolated lab environment.

Among the five COs (Table 2), the Android apps have impact only on the course outcome CO4, since the apps are concerned with the implementation and testing of firewall filtering rules. To compare the achievement of the course outcome CO4 before and after the introduction of the Android apps, four assessment tools that are

related to firewall filtering rule implementation topic have been selected, namely, two quizzes, three lab exercises, two midterm questions, and two final exam questions. The grades of the students in these quizzes, lab exercises, and questions are measured, normalized, and then aggregated using (Eqs. 1 and 2) to calculate the achievement level of the course outcome CO4.

Figure 8 illustrates the achievement of the course outcome (CO4) for six consecutive academic years, from 2009/2010 to 2014/2015. It shows an important improvement in the achievement level of the course outcome CO4 after introducing several new hands-on lab exercises on firewall filtering rules and the two discussed Android apps in fall 2012. The assessment results show that the achievement level of CO4 in fall 2012 improved by about 7%, compared to the achievement level in the previous academic year (2011–2012).

In addition, Table 3 compares the CO4 achievement level of the 2011/2012 and the 2013/2014 academic years in detail. It shows that the 9% improvement in the achievement level of CO4, from 77% to 86%, can be interpreted as 11.9% and 5.9% increase in the number of students scored above 90% and 80%, respectively, and 10.8% and 6.4% drop in the number of students scored below 60% and 70%, respectively.

The aforementioned assessment results clearly show that starting from fall 2012, the achievement level of the course outcome CO4 (which is concerned mainly with the students' hands-on skills on firewall filtering rules implementation) has improved compared to the previous academic year. In principal, this is apparently due to the fact that the introduction of several new hands-on lab exercises on firewalls and the proposed Android apps allowed students to improve considerably their hands-on skills on firewall filtering rules implementation and better anatomized this topic. The students have learned better with the offered Android apps, which had a positive effect on their performance.

However, to show that the introduction of the apps contributed to affect those assessment results, mainly the learning outcome CO4's

Android-Based Mobile Apps for Hands-On Education, Fig. 8 Course outcome CO4 achievement

Android-Based Mobile Apps for Hands-On Education, Table 3 Detailed description of the course outcome CO4 achievement

	CO-4	
	2010/2011 (%)	2013/2014 (%)
CO < 60%	20.0	9.2
60% ≤ CO < 70%	17.8	11.4
70% ≤ CO < 80%	21.9	21.3
80% ≤ CO < 90%	19.6	25.5
90% ≤ CO	20.7	32.6

achievement level, anonymous student questionnaires were administrated to identify the level of impact of the proposed apps on the students' hands-on skills on firewalls. Overall, the questionnaire results supported the fact that the discussed learning platform had a positive impact on improving the students' hands-on security skills on firewalls and consequently contributed to enhancing the achievement of the learning outcome CO4.

Discussion

The following discussion is based on the data collected from 2 anonymous questionnaires

administered to 120 students, who were enrolled in SECB358 course and who over 3 academic years (2012/2013, 2013/2014, and 2014/2015) used the 2 Android apps. The first questionnaire's objective was to measure the students' satisfaction level and collect their feedbacks. The second questionnaire's objective was to identify the locations where the apps have been used and the students' motivations behind using the apps.

In the first anonymous questionnaire, the majority of the students provided positive feedbacks and enjoyed the Android security practices. In fact, most of the students strongly agreed or agreed that Advanced Firewall app contributed significantly to the closeness of firewall technologies to their daily lives and promoted their interests on firewalls (Table 4, Q. 1 and Q. 2).

The results of the questionnaire showed that about 86% of the students who answered the questionnaire felt that Advanced Firewall app to be useful and helped them better understand the theoretical firewall concepts taught in the lecture (Table 4, Q. 3). The questionnaire also revealed that about 85% of the students strongly agreed or agreed that the proposed apps helped them to develop further their hands-on skills (Table 4, Q. 6), and about 91% of the students strongly

Android-Based Mobile Apps for Hands-On Education, Table 4 Student feedback questionnaire results

Question	Response
Q. 1. Do you think that Advanced Firewall app contributed to the closeness of firewall technologies to your daily lives?	2% Strongly disagree 1% Disagree 5% Neutral 8% Agree 85% Strongly agree
Q. 2. Do you think that Advanced Firewall app promoted your interests on firewalls?	0% Strongly disagree 1% Disagree 3% Neutral 5% Agree 91% Strongly agree
Q. 3. Do you feel that Advanced Firewall app is useful and helped you better understand the theoretical firewall concepts taught in the lecture?	4% Disagree 10% Neutral 1% Agree 85% Strongly agree
Q. 4. Do you think Advanced Firewall app offers to you the necessary basic firewall functions learned in the lecture?	3% Disagree 8% Neutral 10% Agree 77% Strongly agree
Q. 5. Do you think Advanced Firewall app offers to you the necessary advanced firewall functions learned in the lecture?	95% Disagree 3% Neutral 2% Agree 1% Strongly agree
Q. 6. Do you feel that Advanced Firewall app helped you to develop further your hands-on skills on firewall filtering rules implementation?	7% Disagree 8% Neutral 13% Agree 72% Strongly agree
Q. 7. How likely are you to recommend Advanced Firewall app to others to practice firewall filtering rules implementation outside the laboratory environment, at their convenience?	5% Disagree 6% Neutral 8% Agree 81% Strongly agree
Q. 8. Would you like to see similar Android apps offered to students for other security topics, such as intrusion detection?	5% Disagree 4% Neutral 18% Agree 73% Strongly agree
Q. 9. Do you think that Packet Generator app helped to test the correctness of your filtering rules?	5% Disagree 4% Neutral 18% Agree 73% Strongly agree

agreed or agreed to see similar Android apps offered to students for other security topics, such as intrusion detection systems (Table 4, Q. 8).

Moreover, most students recommended offering Advanced Firewall app to students to practice firewall filtering rules implementation, outside the laboratory environment, at their convenience, after practicing the traditional hands-on exercises inside the laboratory rooms (Table 4, Q. 7).

Also, the questionnaire results showed that 87% of the students strongly agreed or agreed that Advanced Firewall app offered to them all the necessary basic firewall functions learned in the lecture (Table 4, Q. 4). However, 95% of them strongly disagreed that Advanced Firewall app offered to them all the necessary advanced firewall functions, such as DPI and VPN. This is explained by the fact that the version of Advanced Firewall app offered to students lacked advanced firewall functions (Table 4, Q. 5).

Overall, the questionnaire results support the fact that the discussed Android learning platform had a positive impact on the students' hands-on security skills and consequently would contribute to enhancing the achievement of the course learning outcomes. In fact, the two Android apps allowed students to better anatomize and assimilate the firewall concepts learned from the lecture.

Regarding the second questionnaire (Table 5), the results showed that about 98% of the students used the two Android apps outside the laboratory environment at many locations, mainly at the school and homes (Table 5, Q. 1). In addition, 78% of the students used the apps to prepare for the exams and continued using the apps even after the exams to protect their mobile devices or to practice further (Table 5, Q. 2).

The results of the second questionnaire showed that the major objective of providing an Android-based learning approach to allow students to further practice firewall filtering rules implementation, outside the in-campus isolated laboratory environment, in the real-world, anywhere and anytime, and at the students' convenience, is achieved.

Conclusion

This entry discussed a learning activity that uses two Android apps to enhance students' hands-on

Android-Based Mobile Apps for Hands-On Education, Table 5 Students questionnaire results

Question	Response
Q. 1. Outside the laboratory room, where did you use <i>Advanced Firewall and Packet Generator</i> apps to implement and test firewall filtering rules?	2%: I never used them outside the laboratory room 30%: Only at the school 20%: Only at home 48%: At many locations (Schools, home, and others)
Q. 2. Outside the laboratory room, how often did you use <i>Advanced Firewall and Packet Generator</i> apps to implement and test firewall filtering rules?	2%: I never used them outside the laboratory room 20%: I used them few times to prepare for the exams 78%: I used them many times even after the exams to protect my mobile device or to practice further

skills on firewalls concepts. The main objective is to demonstrate how mobile devices can be used to develop novel educational activities and tools and learning approaches that attempt to get benefit from the prevalence of mobile devices within the student community. The data collected using assessment tools and students' feedback questionnaire demonstrates clearly that the discussed Android-based learning activity had a positive impact on the students' firewall hands-on skills and on the students' performance in terms of achieving the course learning outcomes. Moreover, a comparative analysis of various related Android apps with the discussed apps emphasizes their significance, mainly for the academic environment.

The educational case study presented in this entry demonstrates clearly that mobile technology has the potential to transform considerably the learning field by allowing to develop novel educational activities, approaches, and tools that take advantages of the benefits of this technology and its increase growth in popularity within the student community. Therefore, the existing learning approaches, pedagogical models, and educational tools should reflect the current trend in computing platforms away from the desktop and toward mobile technologies.

Moreover, as institutions adopt new mobile technologies, they should look beyond using these devices for teaching and examine how mobile computing can increase engagement and cultivate strong communities of learners. In fact, mobile computing has the potential to transform learning and engages students in learning in different ways. Consequently, as mobile devices have become more common on campuses, many innovative projects have emerged that engage students and change the way faculty teach courses.

Introduction

The tremendous popularity of mobile computing and Android in particular has attracted millions of developers who see opportunities for building their own start-ups. As a consequence computer science students express an increasing interest

into the related technology of Java development for Android applications. Android projects are complex by nature and relatively large software products, while their development calls for the application of established software engineering practices and tools.

Computer science and information technology curricula include software engineering as a key knowledge area (ACM 2013), and as a result, most computer science-related departments offer at least one “conventional” software engineering course. By conventional we mean that in most cases, the introduced concepts are exemplified on either desktop applications standing individually on a personal computer and recently on web applications employing server and/or client side development. To the best of our knowledge, there are very few courses that introduce software engineering concepts to a mobile software development course. At the same time, software development for particular platforms is often perceived and taught as a purely technological skill with no direct connections to software engineering. The consequence is that even experienced mobile application programmers do not embrace or apply software engineering practices. Moreover, the lure of Android development can serve as a vehicle for conveying software engineering concepts to computer science students in an attractive way. All these issues have resulted in interesting proposals regarding the integration of mobile devices into the computer science curriculum and relevant courses and teaching approaches.

The integration of mobile devices into the computer science curriculum has been discussed in a study by Mahmoud (2008) where the need to consider the important factor of restricted resources (small screen, limited memory, etc.) is stressed. Moreover, the author highlights the difference of compiling an application for a “normal” PC and for a mobile device. It is claimed that introducing mobile devices and the basics of mobile application development as early as possible in introductory programming courses is a necessity. In the context of the described course, the students were asked to develop two versions of a mortgage calculator application: one for a

desktop and one for a mobile platform, so they could distinguish the differences (and similarities) between the two approaches.

A different approach is adopted in the work of Akopian et al. (2013) where the authors rely on already developed templates (Android programs) to teach in a short course, the basic principles of Android development. The students were asked to alter specific aspects in the program by modifying the existing code. The questions and activities have been very carefully structured and explained, in order to guide the student to the correct position of variable or code snippet that needs to be changed. Through structured colored examples, the activities for the students are slowly escalating to the most difficult ones. According to one pre-course and one post-course survey, student’s satisfaction has been achieved along with a strong belief that basic skills have been obtained through the course.

Evidence from evaluations performed by Heckman et al. (2011) implies that teaching lower-level programming courses with more advanced and current technologies such as mobile devices can be beneficial. In particular, the authors taught Java and software engineering courses at the University of Virginia and North Carolina State University utilizing the Android OS platform. Although details about the course are not provided, the goals are similar to the proposed course in this paper, i.e., to teach both Java (such as abstraction) and software engineering concepts (such as design, testing, and patterns) using Android.

Petkovic et al. in 2006 (Petkovic et al. 2006) claimed that practical teaching of software engineering should also focus on teamwork, communication skills, and organizational issues to reflect the globalization and open-source aspects of real software development projects. The authors recommend that students should be divided into small groups of four to six persons in order to simulate real-life software development and undertake the task of constructing a web application through five milestones. The course also emphasizes the need of collaboration without face-to-face meetings, and to this end, the use of version control systems is essential.

The main motivator for their work was that the combination of traditional classroom teaching of processes, teamwork, and communication with a major final project, intensive instructor interaction, and realistic simulation of real software lifecycle is critical. The benefits of cooperative learning where students work together in small groups enhancing each other's learning have been recognized early in the computer science education community (Tenenbergh 1995). The same belief is shared by the authors of the current work and has been taken into account during the design of the proposed course.

The challenges of designing a smartphone software development course based on Android have been discussed by Hu et al. (2010). The paper introduces a full semester course with an emphasis on the underlying platform: the first two parts of the course consist in an introduction to smartphones and their OS. The next three parts are presenting the environment for Android development, while only the seventh part is devoted to software development. The authors are acknowledging three design principles with the second stating that the teaching content should place an emphasis on practice rather than theory and the third mentioning that course contents should meet the needs of the industry.

In this entry, a short course is introduced aiming at illustrating selected software engineering principles, concepts, and techniques in the context of Android application development. The goal is to demonstrate that Java programming for Android applications – which is usually perceived as an isolated activity – can benefit largely from applying software engineering best practices. The course is structured around a base Android application that is gradually enhanced by discussing limitations or opportunities that can be addressed by appropriate techniques or guidelines such as design principles, design patterns, refactorings, software metrics, testing, version control systems, etc. The proposed course has been evaluated with positive results (Chatzigeorgiou et al. 2016), and it is in accordance with the findings of the Joint Task Force on Computing Curricula of the IEEE Computer Society and the Association for Computing Machinery

(ACM) (LeBlanc and Sobel 2004), where a set of guidelines for effective education activities have been established. These guidelines emphasize the need to focus on professional issues necessary to begin practice as a software engineer and the need for students to complete tasks that involve both individual work and tasks that require collaboration among peers. Having this in mind, students were divided into small groups as described in (Petkovic et al. 2006), with the exception that they were left alone to form the groups. This approach seemed more appropriate to the Arabic or the Greek cultures, where students tend to lean toward the existing bonds among them.

The rest of the entry is outlined as follows: section “[Introduction](#)” presents an outline of the proposed course; the detailed structure along with the introduced software engineering concepts and the activities carried out at each step. Section “[The Course](#)” provides some guidelines for an effective application of the proposed course, and section “[Guidelines for Delivering the Course](#)” provides the final conclusions.

The Course

Learning Outcomes

The proposed course aims at introducing software engineering concepts and techniques in the context of Android development. The course can be delivered either in an advanced undergraduate or a postgraduate program. In case students have a background in both areas (software engineering and Java/Android development), the objective is to highlight that mobile application development can benefit from the adoption of best practices as learned in a software engineering course. In case students lack background in any of the involved areas, the course can also serve as an introductory seminar for the corresponding topic, given that it includes theoretical aspects as well as lab activities.

The short course is in agreement with the 2013 Curriculum Guidelines for undergraduate programs in computer science by ACM (2013) where Platform-Based Development (PBD) has been elevated to a Knowledge Area (KA) in the

Computer Science Body of Knowledge. The guidelines suggest that electives should be offered (in the area of programming interactive systems) covering the needs for specific programming paradigms and mobile development and these are designated as “high-demand” courses. Within the ACM report, it is noted that platform-based development as a general skill of developing with respect to an Application Programming Interface (API) or a constrained environment is directly related to other knowledge areas such as Software Development Fundamentals (SDF). As a result, the relationship between mobile development and software engineering is profound.

According to the constructive alignment approach (Biggs and Tang 2011), it is important to start reasoning about the outcomes that a planned course aims at achieving and then align the teaching and assessment strategies to those explicitly stated outcomes. Learning outcomes are statements of what a learner is expected to know, understand, and/or be able to demonstrate after completion of a lecture, course, or entire program. Compared to teaching aims or objectives, outcomes offer the advantage of being more precise, clearer, and easier to compose (Kennedy et al. 2006).

We formulate the learning outcomes of the proposed short course as follows, placing them in the appropriate knowledge and cognitive process dimension of the revised Bloom’s taxonomy (Krathwohl 2002) in Table 1:

1. Explain the benefits from applying software engineering practices to Android development.
2. Apply design principles and design patterns in Android applications.
3. Identify and resolve design issues in Android applications.

Informed choices regarding the curriculum have to clearly define the desired Information and Communication Technology (ICT) skills, besides the underlying knowledge area(s) and learning outcomes. A tool that can be used for this purpose is the Skills Framework for the Information Age (SFIA), which provides 6 categories and 19 subcategories including 96 ICT-specific skills in total (SFIA Foundation 2015). These skills are defined quite generally and independently of the underlying knowledge areas, so that they are transferable to different ICT domains/disciplines. In addition to the general definition, SFIA provides a definition of each skill across the following seven levels of responsibility (that apply in each case): (1) follow; (2) assist; (3) apply; (4) enable; (5) ensure and advise; (6) initiate and influence; and (7) set strategy, inspire, and mobilize. Utilizing a tabular approach (Herbert et al. 2013), the main SFIA skills that the proposed course aims at are presented in Table 2.

The course is structured around a base Android application that is gradually enhanced over 13 consecutive steps. At each step a different software engineering concept, practice, or technique is introduced which is then exemplified through additions to the functionality of the application or restructuring of its design.

In accordance to Keller’s Motivation Theory (Keller 1983), the course is designed in order to promote learning by increasing students satisfaction and attention. A feeling of satisfaction is achieved by providing students with opportunities to apply on a small, but real Android application the newly learned knowledge and the interest of the students is engaged by interleaving different software engineering practices and techniques on the same example. Since the course is structured

Applying Software Engineering Principles in Android Development, Table 1 Course learning outcomes in terms of the revised Bloom’s taxonomy

Knowledge dimension	Cognitive process dimension					
	1. Remember	2. Understand	3. Apply	4. Analyze	5. Evaluate	6. Create
A. Factual knowledge		(1)				
B. Conceptual knowledge		(1)	(2)	(3)		
C. Procedural knowledge			(2)	(3)		
D. Metacognitive knowledge

Strategy and architecture ~ Technical strategy and planning	Methods and tools (<i>Ensuring that appropriate methods and tools for the development, testing and maintenance of systems are adopted</i>)	4 – enable 5 – ensure, advise	METL

*Refers to the unique skill code in the SFIA Framework

around a central lab activity which is gradually enhanced, it adheres to the learning theory of “Learning by Doing” which is one of the most well-known theories (Dewey 1938). Instructors can decide on the importance/time that should be placed on the theoretical presentation of each software engineering concept or technique and the corresponding hands-on assignments, depending on the subjects’ background. The particular contents of each step are discussed in the next section.

Course Structure and Activities

As already mentioned, the proposed course is structured as a series of incremental additions to an initial Android application with the goal of introducing a different software engineering principle, concept, or technique each time. The outline of the course is shown in Table 3, depicting the corresponding students’ activity in each step, the functionality of the resulting Android Java application as well as the introduced concept. A detailed presentation of the introduced software engineering concepts, as well as the corresponding activities, is provided in the following paragraphs.

Step 1: MVC Pattern

The Model-View-Controller architecture (or pattern) is fundamental to various domain-specific

architectures that entail a significant amount of interaction with the user (Ghezzi et al. 2002). The architecture suggests the use of three different components: (1) the model that manages the data of the application domain, (2) the view that takes over the graphical display of the model, and (3) the controller that interprets user actions and coordinates the view and the model. A partial illustration of the MVC pattern can be achieved with the use of `ListView` objects in Android, which show items in a vertical scrolling list. A `ListView`, as any other View in Android, is built as a separate layout XML file and plays the role of the View component in MVC. Lists are populated by retrieving data from appropriate adapters which essentially control the content displayed in the list and the way it is displayed (Controller component of the MVC). The data itself can reside in a separate object as in the proposed example and constitutes the Model component of MVC. The separation of components according to MVC is shown graphically in Fig. 1.

Step 2: Externalization of Resources

Android encourages the application of a valuable practice, namely, the externalization of non-code resources like images and string constants or even entire layouts. Keeping resources separate from source code enables easier maintenance,

Applying Software Engineering Principles in Android Development, Table 3 Course structure

	Students' activity	Functionality of the resulting software	Introduced software engineering concept/technique
1	Downloading of initial version	Listing of future appointments in ListView	Model-View-Controller pattern Ghezzi et al. (2002)
2	Introduction of Android activity	Addition of input screen	Externalization of resources Mednieks et al. (2012)
3	Development of task hierarchy	Submission of tasks to ListView	Use of inheritance for modeling similar entities Liskov substitution principle Liskov and Wing (1994)
4	Intent handling	Display of task description and date and selection of appropriate color for each task type	Use of polymorphism. Open-Closed Principle Martin (2003)
5	Preservation of state between invocations of an activity	Display of multiple tasks in the ListView	Singleton design pattern Gamma et al. (1995)
6	Use of TreeSet structure for ordering	Ordering of tasks based on their date	Dependency inversion principle (use of TreeSet class – implementation of the Comparable interface)
7	Installation of metrics plugin. Examination of metric values	No change. Assessment of quality	Software metrics and their use for software quality evaluation. Software ageing
8	Identification of code smells	No change. Assessment of quality	Code smells (large method)
9	Unit test preparation	No change	Unit testing. Regression testing
10	Refactoring application Execution of unit tests	No change. Design improvement	Refactorings as a means to improve software. (extract method refactoring)
11	Addition of code. Identification of smell. Refactoring application	Setting task description text to title case	Smells + refactorings (extract method/move method)
12	Committing to a Git repository	No change	Distributed version control
13	Uploading to a common remote repository. Downloading by different students, edits, and merging. Viewing history	Any modification is acceptable	Collaborative software development

updating, and management. For example, internationalization can be easily supported having Android automatically select the appropriate resource values depending on the device's specific language or country, without having to modify the source code that manipulates these resources. The students' activity in this step consists in the creation of a simple Activity (by interacting with the layout) and placing emphasis on the externalization of string values that specify the text to be displayed for each graphical component. The corresponding process is depicted graphically in Fig. 2. After changing the introduced activity to a launcher activity, when the application starts, it

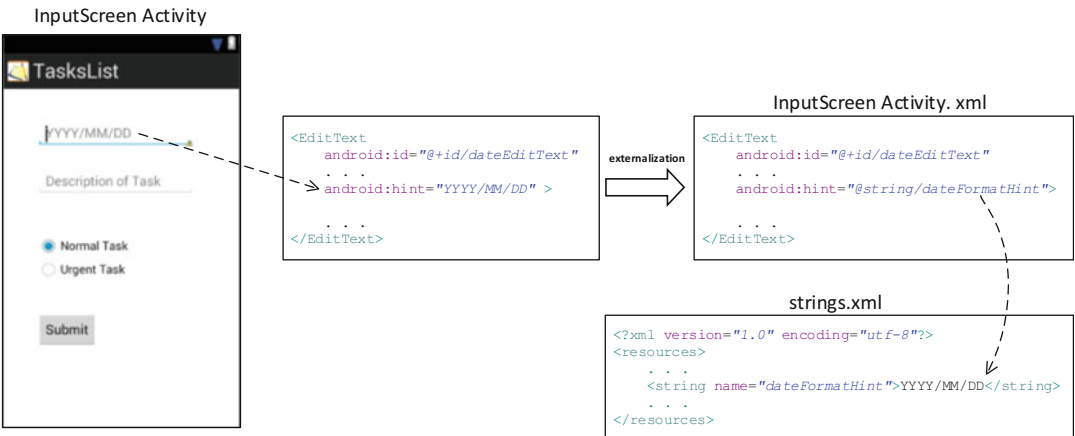

displays the simplified input form for adding new tasks (without any functionality in the submit button so far).

Step 3: Use of Inheritance for Modeling Similar Entities

The next step in the proposed example consists in the addition of functionality to the "submit" button, so that whenever a new task is added, it will be displayed on the `TasksView` activity. The essence of this step is not the linking of a button to a class method – which is rather straightforward – but rather the need to highlight that classical object-oriented concepts, like inheritance

Applying Software Engineering Principles in Android Development, Fig. 1 Illustration of the Model-View-Controller pattern in the context of a ListView

Applying Software Engineering Principles in Android Development, Fig. 2 Introduction of Activity and externalization of strings

and abstraction, can be applied to Android applications as in any other kind of project that the students learned in the corresponding object-oriented programming courses. Once the “submit” button is pressed, the information concerning the added task (date, description, and urgency in this simplified example) should be transferred to the `ListView`, along with an intent that will cause the appearance of another activity’s view (Mednieks et al. 2012). A large number of Android developers would simply transfer this information in the form of individual strings, missing the

opportunity of taking advantage of an appropriate Task hierarchy. All pieces of information can be embedded into an appropriate Task object, whose class will designate the actual type of the task. Apart from the structural improvement to the source code that improves readability, the use of an inheritance relationship as shown in Fig. 3 will enable the use of polymorphism and the adherence to the “Open-Closed Principle” as it will be shown later. To make the distinction more clear, we assume that for urgent tasks the corresponding background in the `ListView` will be red (blue

for NormalTasks) and that the description of each task will have as prefix the urgency of the task (“Urgent,” “Normal”).

In order to have task objects be conveyed by the intent that will be emitted, the corresponding Task classes should implement the `Serializable` interface. It is reminded that this is a marker interface, which means that it does not contain any methods that have to be implemented. A class implements this interface simply to indicate that its non-transient data members can be written to an output stream. The abstract superclass in Fig. 3 declares two abstract methods which are implemented in a different way in each of the subclasses. The functionality of the application after the completion of this step enables the user to add a new task and view the corresponding description in the `ListView`. Only a single task can be viewed at this point.

The class related to the input screen – whenever the submit button is pressed – reads the information in the input text fields and, depending on the selection of the radio buttons, instantiates either a `NormalTask` or an `UrgentTask` object. Then, an `Intent` is sent to the Android system defining explicitly the class that should be invoked (`.class`), and the instantiated task object is passed within the intent.

The `TasksView` class (containing the `ListView` object) receives the intent and retrieves its content without knowing which kind of task has been included. The received task

object is assigned to a Task reference and transferred to the corresponding data model.

At this point, students should be reminded about the “Liskov Substitution Principle” (Liskov and Wing 1994) according to which “derived types must be completely substitutable for their base types.” In other words, any method, class, or system that handles objects of a superclass should operate properly even when objects of subclasses are used. In the context of the examined application, a reference to the Task class can receive an object of any of its subclasses, namely, `NormalTask` or `UrgentTask` objects, since a generalization is an “is-a” relationship meaning that `NormalTasks` and `UrgentTasks` are also Task instances. This concept is illustrated in Fig. 4.

Step 4: Polymorphism and Open-Closed Principle

The real benefit from the use of polymorphism becomes evident when the handling of the received intent is performed in the `TasksView` class in order to display the newly added task. The `TasksView` retrieves the Task object from the intent and stores it in the corresponding data model. Within the adapter method which is responsible for filling in the corresponding line items of the `ListView`, the color for the background of each task is obtained by a call of the form:

```
Task task = (retrieved from the
intent)
. . .
int color = task.getBackgroundColor();
```

Applying Software Engineering Principles in Android Development,
Fig. 3 Task hierarchy

Applying Software Engineering Principles in Android Development, Fig. 4 Liskov Substitution Principle in the context of the examined application

Method invocation `task.getBackgroundColor()` is a polymorphic method call, since dynamic binding will be employed to invoke the appropriate method of the corresponding Task subclass, depending on the actual type of the object to which reference `task` will be pointing to at runtime. Students get the opportunity to understand that this essential feature of object-orientation – which is rarely employed in Android applications – can be easily integrated with the rest of an application’s functionality.

At this point, the “Open-Closed Principle” of software engineering (Martin 2003) according to which “software modules should be open for extension (of functionality) but closed to modification (of existing source code)” can be reintroduced. The client of the Task hierarchy which is the Adapter/View part of the system can be extended (e.g., new kinds of Tasks can be added with different functionality in terms of background color or description formatting) without the need to modify even a single line of the code that handles the tasks. The “Open-Closed Principle” is illustrated in Fig. 5.

Step 5: Singleton Design Pattern

The application so far suffers from a rather serious drawback: only one task is displayed regardless of how many are introduced in the input screen. The reason is that whenever the `TaskView` activity is invoked by a new intent it leads to the construction of a new adapter associated therefore with a new data model, and previous tasks are lost. In other words there is no preservation of state between activity invocations.

Although in a real application data would be directly stored into a database to allow persistence, at this point it would be very useful to remind the notion of design patterns as a means

of resolving commonly recurring problems by reusing previous experience (Gamma et al. 1995). In this particular case, the Singleton design pattern offers an elegant solution to the problem of data preservation. The goal of this pattern is to ensure that only one instance of a class is created and that a global access point is provided to that object (Gamma et al. 1995). Turning the Model class which holds the list of tasks to be displayed to a Singleton ensures that at any time the same, unique data model is used. In terms of functionality, the application allows the display of numerous tasks.

Step 6: Dependency Inversion Principle

So far, the application displays tasks in the order in which they have been added to the input screen. Obviously, there is a need for ordering tasks according to their date. This can be easily accomplished employing a data structure in which stored elements are automatically ordered. An appropriate Java data structure is the `TreeSet` where elements are retrieved based on their natural ordering. For any domain-specific class like the Task class the developer should specify the way in which tasks should be ordered by implementing the `Comparable` interface and overriding the `compareTo()` method (or alternatively by providing an appropriate `Comparator`). In this particular case, the `compareTo()` implementation can simply delegate the responsibility of comparing two tasks to their included `Date` objects. The resulting functionality at this point is a listing of tasks according to their date, i.e., closer tasks in time are displayed first.

While this is a rather widely known technique to Java developers, it would be important to emphasize that the designers of Java essentially adopt the “Dependency Inversion Principle”

Applying Software Engineering Principles in Android Development, Fig. 5 Open-Closed Principle in the context of the examined application

(DIP) (Martin 2003) in this context. The DIP principle states that “High-level modules should not depend on low-level modules. Both should depend on abstractions”. In other words, high-level modules such as the implementation of the `TreeSet` class, which should be agnostic of the particular items that will be stored in the structure, should be decoupled from the corresponding classes, and this is achieved by declaring that `TreeSet` handles `Comparable` objects. Any class, whose objects should be stored in a `TreeSet` will therefore have to comply with the `Comparable` interface and provide an implementation to its single method taking care of the comparison between two objects. The philosophy of the DIP principle in the context of the `TreeSet` is illustrated in Fig. 6. The principle is of extreme importance for enabling the development of maintainable systems and especially APIs, and this sets an excellent opportunity for introducing the resulting benefits of DIP application to the students.

Step 7: Metrics for Software Quality Assessment

At this point the application has a reasonably large number of lines of code and methods. Moreover, the continuous evolution in terms of functionality enhancements highlights that Android applications are by nature evolving software projects. In order to assess whether the qualities of the underlying design deteriorate or not over time, software metrics can be employed as in any other type of software system. Students should be reminded about the challenges associated with software maintenance and the possibility of software

ageing (Parnas 1994). From the perspective of quality assurance, monitoring software qualities by means of appropriate software metrics can offer significant help in preventing the accumulation of the so-called technical debt (Cunningham 1992).

At this step students should install a metrics collection and analysis tool, preferably one that is integrated into the employed IDE in order to assist the next steps related to preventive maintenance. Students can obtain a first impression and reason about the properties of the design by assessing metrics related to size, complexity, coupling, and cohesion. Indicative results are shown in Table 4. It is important to discuss the concept of aggregating metric values from one software level (e.g., methods) to the next (e.g., class, package, or system).

Step 8: Code Smells

According to Fowler (1999), deeper problems in the system structure often manifest themselves in the form of easily identifiable code smells, i.e., surface indications that something might be wrong at the code or design level. Hints for the presence of several smells can be provided by excessive metric values or values that deviate from the mean. As an example it can be observed that method `getView()` in the `TasksAdapter` class is much longer than the rest of the methods in that class and has a higher complexity and a larger number of parameters, a potential indication of a “long method” smell (despite the fact that in this case the smell is rather weak and presented only as an example). A long

Applying Software Engineering Principles in Android Development, Fig. 6 Dependency Inversion Principle in the context of the examined application

Applying Software Engineering Principles in Android Development, Table 4 Sample metrics related to the Android application at the method and class level

Class/method		LOC (lines of code)	Number of parameters (per method)	CC (cyclomatic complexity per method)
TasksAdapter		18	1.0	1.167
	TasksAdapter()	1	0	1
	addTask()	1	1	1
	getCount()	1	0	1
	getItem()	1	1	1
	getItemId()	1	1	1
	getView()	13	3	2

method refers to a piece of code that is large in size, noncohesive, and relatively complex. A method with these symptoms might be difficult to comprehend, modify, test, and reuse (although for the size and complexity of the examined applications, these problems might seem too distant).

For the case of the long method, the designer should assess the intensity of the problem. This is often related to whether the method takes over more than one responsibilities. Different responsibilities might be subject to different “axes of change,” implying that part of a method’s body might be modified although the rest of the method’s functionality should remain unchanged, often leading to the propagation of errors from one

part to another. As an example, consider the method `getView()` of class `TasksAdapter` which has already been identified by the application of metrics as a larger and more complex method, in comparison to the rest of the methods in that class. Although its logic is quite simple, it contains two distinct responsibilities which are highlighted in the code fragment of Fig. 7: (a) the inflation of a new view object from the corresponding XML resource (in this case a single task list item containing the description and date of each task) and (b) the population of this view based on the information that can be retrieved from a task object. This case could be regarded as a symptom of the “long method” smell.

```

public View getView(int index, View view, ViewGroup parent) {
    if (view == null) {
        LayoutInflater inflater = LayoutInflater.from(parent.getContext());
        view = inflater.inflate(R.layout.tasks_list_item, parent, false);
    }

    Task task = model.getItem(index);

    TextView descriptionTextView =
        (TextView) view.findViewById(R.id.description_view);

    descriptionTextView.setText(task.getDescription());

    TextView dateTextView = (TextView) view.findViewById(R.id.date_view);

    dateTextView.setText(task.getDateText());

    int color = task.getBackgroundColor();

    descriptionTextView.setBackgroundResource(color);
    dateTextView.setBackgroundResource(color);

    return view;
}

```

inflates view from the specified xml resource

populates the view with retrieved task data

Applying Software Engineering Principles in Android Development, Fig. 7 Pseudocode for getView() method highlighting the different functionalities

Step 9: Unit Testing

According to the famous quote by Dijkstra, the aim of testing software systems is to reveal the presence of errors which in turn might lead to system failures (Dahl et al. 1972). One of the most effective approaches for testing large and complex systems consists in the execution of unit tests, where the goal is to compare the expected behavior of individual software modules (e.g., classes) to their actual one. The most important benefit from the construction of a set of unit tests is the ability to perform regression testing, which means that the system can be tested for possible errors after any slight modification, providing a certain degree of confidence that maintenance has not introduced additional errors.

At this step of the proposed course, students are asked to generate test cases for the TasksAdapter class, prior to any attempt of improving the class structure, since a smell has been identified in one of its methods. The testing framework of choice to support the preparation

and execution of test cases is JUnit (<http://junit.org>) which is an open-source, widely acknowledged and easy-to-use unit testing environment integrated into the Eclipse IDE. Test cases are written in the form of method invocations with selected parameter values and known results. A test case succeeds if the examined method fed with the selected parameters behaves as expected.

In this particular case, the goal is to test the behavior of the getView() method of the TasksAdapter class. However an adapter is always associated with the corresponding Activity containing a ListView object, so the goal is to add a task to the ListView and inspect whether the getView() method returns the correct task. To perform tests for activity unit testing, one should create a subclass of the ActivityUnitTestCase and initiate an Intent to trigger the desired activity (Android Developers 2013). The test case that contains a unit test for the getView() method of class TasksAdapter is shown in Fig. 8.

Code Under Test (Adapter)

```
public class TaskAdapter extends BaseAdapter {  
    private Model model;  
    ...  
    public View getView(int index, View view,  
        ViewGroup parent) {  
        //constructs a view for each listView item  
        //and populates it with information  
        //retrieved from the corresponding Task  
    }  
}
```

Activity with ListView

Test Case (unit test targeting getView () method of the Adapter)

```
public class TaskViewTest extends ActivityUnitTestCase<TaskView> {  
    private TaskView activity;  
    private ListView listView;  
    ...  
    protected void setUp() throws Exception {  
        super.setUp();  
        Date date = ... //create a Date object 2014/05/21  
        Task newTask = new NormalTask(date, "SampleTask");  
        //initiate the TaskView activity feeding it with the newTask  
        Intent intent = new Intent(  
            getInstrumentation().getTargetContext(), TaskView.class);  
        intent.putExtra("Task", newTask);  
        startActivity(intent, null, null);  
        //retrieve the activity and the enclosed listView object  
        activity = getActivity();  
        listView = activity.getListView();  
    }  
    //test whether the listView (i.e. the associated adapter)  
    //retrieves the correct task  
    public void testGetView() {  
        Task task = (Task) listView.getItemAtPosition(0);  
        assertEquals("Normal: SampleTask", task.getDescription());  
        assertEquals("2014-05-21", task.getDateText());  
    }  
}
```

Applying Software Engineering Principles in Android Development, Fig. 8 Unit testing for Android activity/adapter

Step 10: Refactoring Application (Extract Method)

Now that the source code is equipped with test cases, developers can attempt to improve the design by applying appropriate refactorings. After any change, the test cases can serve as a checkpoint against which functionality can be verified. A refactoring is a way to improve the internal structure of software without changing its observable behavior (Fowler 1999). In most cases, refactorings are applied in order to resolve code smells that have been identified. Refactorings have been widely embraced by software developers mainly because of the simplicity in applying them. Currently, numerous IDEs provide support for the automatic application of refactorings relieving the designers from the burden of their mechanics (Murphy-Hill et al. 2009). Although the impact of a single refactoring might seem limited, the cumulative effect of successive refactorings on design quality can be significant.

Test cases can guarantee (with a certain degree of confidence) that any modification to the design has not altered the functionality of the methods. Returning to the “long method” smell observed for the `getView()` method of the `TasksAdapter` class, the appropriate refactoring would be to split the existing method in two more cohesive methods. According to Fowler’s catalog (Fowler 1999), this corresponds to the “Extract Method” refactoring, whose goal is to “turn a fragment of code into a method whose name explains the purpose of the method.” For the `getView()` method, the functionality related to the retrieval of information from the `Task` object in order to populate the view’s contents can be extracted as a separate `populateView()` method, which will be invoked by the original method as shown in Fig. 9. The Eclipse IDE can automatically apply the Extract Method refactoring by simply designating the fragment of code that needs to be extracted and automatically identifies the parameters that have to be passed from the original to the extracted method. The application of the JUnit tests validates that the application of the refactoring did not break the existing functionality. As it can be deduced, the resulting methods are smaller, less complex, and more cohesive than the original one.

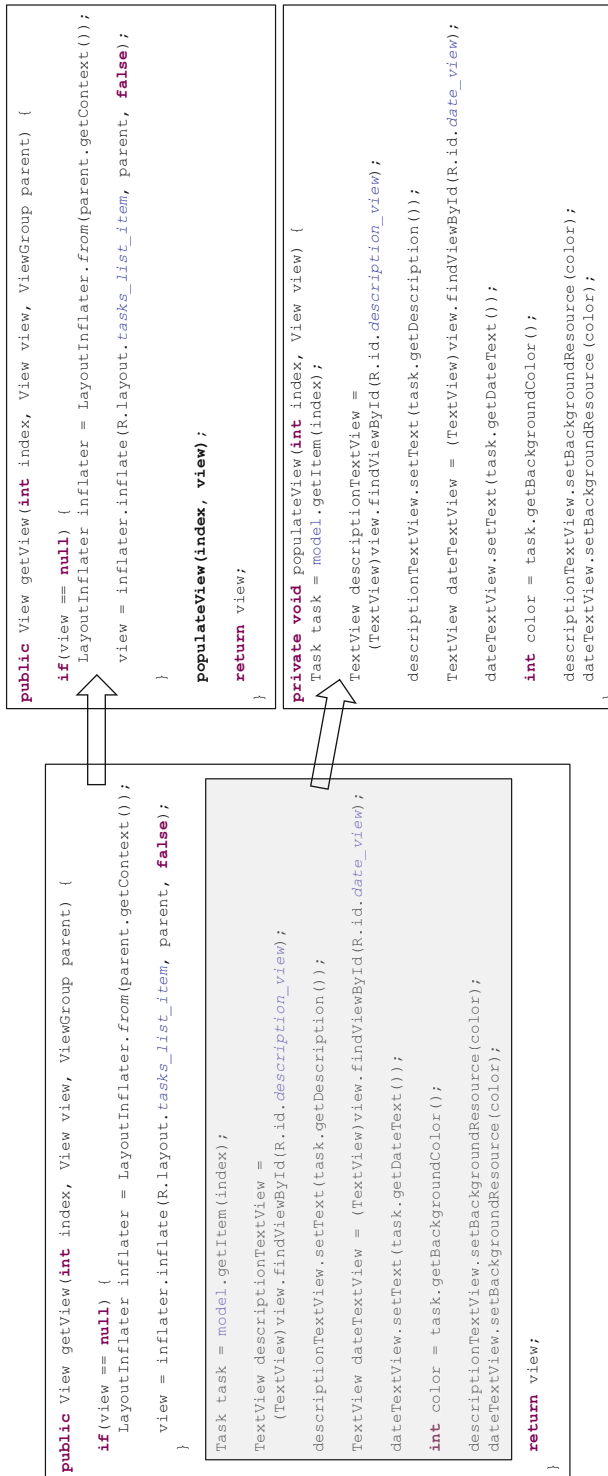

Step 11: Refactoring Application (Extract Method + Move Method)

As software evolves, additional functionality is gradually added to address the needs of clients. Let us assume that the `populateView()` method of the `TasksAdapter` has been enhanced in order to display the description of the forthcoming tasks in title case (Fig. 10). The method’s code has once again become large and relatively complex, and since the conversion of a string to title case is a rather distinct responsibility, it should be extracted as a separate method by applying the Extract Method refactoring as previously (Fig. 10).

However, in this case the extracted method `convertToTitleCase(Task task)` has nothing to do with the `TasksAdapter` class in which it resides. The method accesses only methods from another class, and this is a clear symptom of the “Feature Envy” smell, which according to Fowler (1999) exists when “a method seems more interested in a class other than the one it is in.” The appropriate refactoring to address this design problem is the “Move Method” which consists in moving the method to the target class. In this case the `convertToTitleCase()` method should be moved to the `Task` class, where it also belongs conceptually, since the ability to format the description of a task is related to the task itself, rather than any other class. Eclipse IDE provides support for this refactoring and automatically identifies the `Task` class as the target for moving the method. The existence of the unit tests enables the validation that the application of the refactoring keeps the functionality intact. The series of two refactorings is graphically illustrated in Fig. 10.

Step 12: Distributed Version Control Systems

Software systems are multi-version projects that continuously undergo adaptive, corrective, and perfective maintenance. Even the simplified example outlined in this entry has evolved over a number of versions. An essential part of each software project is its configuration management which deals with tracking and controlling changes in software artifacts, including revision control.

Applying Software Engineering Principles in Android Development, Fig. 9 Extract Method refactoring

Version Control Systems (VCS) refer to software that allows the management and monitoring of changes that occur in any artifact of a project during its initial development or maintenance (Spinellis 2003). Version control offers significant benefits to the development team, including the ability to retrieve and compare either the entire project or individual files created at any time point, access to a log of all past changes, and under certain conditions support for collaborative software development.

Nowadays, it is hard to find an industrial project that is not backed up by a VCS, and thus it would be extremely beneficial to introduce students to the corresponding practices. It should be mentioned that the use of a VCS exhibits several challenges which cannot be covered by a short course. In the proposed example, the goal is to highlight the key benefits from using a VCS. Due to its widespread adoption, emphasis is placed on distributed VCS such as Git (<https://git-scm.com/>). Although distributed VCSs can also share a common remote repository, they adopt a peer-to-peer approach where each peer has his own full-fledged repository with complete history and the use of version tracking does not depend on access to a central server. The Git functionality can be accessed through the EGit Eclipse plug-in and thus be integrated in the IDE used for development.

At this step of the course, students are asked to install EGit, create a Git repository, and commit the project to the repository. Details about EGit usage can be found at the corresponding EGit documentation (<http://www.eclipse.org/egit/documentation>). Students are asked to enter a log message that will be attached to each individual

commit. Once the commit is performed, students will be able to track the history of the project as shown in Fig. 11. Students can be introduced to the concept of the main development branch (master), the HEAD pointer referencing the branch that the user is currently on, the importance of good commit messages, and the unique identifier assigned to each Git commit object in the form of a SHA-1 hash value.

Step 13: Collaborative Software Development

Contemporary software development teams consist of members which often are not located in the same geographical area and might even be working at different time zones. To enable the collaboration between multiple developers, VCSs require the use of a common, remote repository that can be used for sharing software artifacts to the rest of the team. A popular hosting provider for Git projects is GitHub (<https://github.com/>) and can be used for the proposed course since public repositories are hosted for free. The instructor (or any student) can create a repository and add fellow students as collaborators to the project (such a project has been created for this course at GitHub).

Students can now start experimenting with collaborative software development based on the Android project that has been developed so far. For example, the instructor can push his own Android project to GitHub and allow students to clone the existing version. Students can simulate the automatic resolution of conflicts when two developers modify at different times two different files and commit and push them to the remote repository. The system will automatically deduce the reasonable course of action which is to accept

Applying Software Engineering Principles in Android Development, Fig. 11 Use of the local repository in EGit

Applying Software Engineering Principles in Android Development, Fig. 12 Handling of conflicts during collaborative software development

and merge the changes. However, in the case when two students make edits to the same file, a conflict will be raised when the second student attempts to commit and push his work. The second student will be informed about the conflict and be prompted to choose one edit over the other or revise the affected lines entirely (such a case is illustrated in Fig. 12). The fact that a VCS can handle similar situations can be an extremely valuable asset in mobile software development.

Guidelines for Delivering the Course

The proposed short course has been delivered to three groups of undergraduate and postgraduate students at two different institutes (Table 5). The course has been evaluated: (a) by performing a student satisfaction survey, (b) by summatively assessing students' performance, (c) by investigating whether the proposed course modified the students' career interests, and (d) by employing assessment by peers based on rubrics. The results are presented in detail in a previous paper (Chatzigeorgiou et al. 2016) and indicate that such a short course is capable of increasing student's interest on Android development as well as

their awareness of the importance of software engineering concepts on mobile application software development. Based on the accumulated experience and the results of the course's evaluation, some guidelines are provided for a more successful teaching.

Utilize a Wiki Page for Supporting the Teaching Process and Communication

A wiki is a web application that gives the chance to collaborate online (Parker and Chao 2007), while it supports online classroom management and offers peer and self-assessment features (Schwartz et al. 2004).

In order to support the teaching process and the communication among students and instructor, a wiki page was developed when delivering the proposed course using as a development environment "Wikispaces" (www.wikispaces.com). Moreover, in order to develop and conduct the online assessment (multiple choice questions) in this course, the "ThatQuiz" online examination system was used (available through <http://www.thatquiz.org>).

The wiki page that was developed for the proposed course can be viewed from the following perspectives:

Applying Software Engineering Principles in Android Development, Table 5 Details of groups to which the course has been delivered

Group ID	Degree	Department	University/ college	Enrollment	Prior Java course	Prior Android course	Prior SE course
1	Undergraduate	Information Technology	Institute 1	16	Yes	No	No
2	Undergraduate	Computer Science	Institute 2	30	Yes	No	No
3	Postgraduate	Computer Science	Institute 2	12	Yes	No	Yes

- *A content delivery system*: providing course objectives, guidelines for the required software infrastructure, and a course outline. The course outline consists of hyperlinks to webpages that provide an overview of the objectives for each step, an explanation on how these objectives can be achieved, additional educational material such as PowerPoint presentations, as well as a link to download the appropriate source code example that is needed for the corresponding step.
- *An online examination platform* that gives students the chance to download the exam as a document file that can be printed and answered offline or connect to the online examination system and get immediate feedback for their answers.
- *A forum* allowing online discussion where participants can hold conversations, post messages, and questions regarding the course.

Take into Account Students' Prior Knowledge

To ensure a smooth progression of the course, the instructor should be aware in advance of the students' level of knowledge and skills in both software engineering and Java development. Ideally, the proposed course should be delivered right after a software engineering course, or at least a course related to Object-Oriented Software Development.

Provide the Appropriate Time for Students to Assimilate the Content

Covering all of the introduced concepts and techniques and carrying out the related activities require no less than 12–16 teaching hours, depending on the students' background.

Provide the Necessary Software Infrastructure

The course relies on a multitude of tools such as the Eclipse IDE for programming, Android SDT, tools for unit testing, metrics calculation, refactoring application, version control, and possibly computer-aided software engineering (CASE) tools. Using a lab where the workstations are ready to use can help students focus on the learning goals. Also, running the course in a lab where all workstations can be accessed from each other or from a central server is important, since it might be often required to deliver one working version of the project to all students.

Try to Keep Students Synchronized

The course is structured as a series of small incremental steps, exactly as it would occur during the actual development of a software project in a small team. Given that the students have often a completely different working pace from each other, it is really challenging to keep them synchronized, but at the same time, it is important in order for them to remain focused.

Try to Monitor Students' Participation

As in any other programming course, student participation should be a key objective of the course. Students can actively participate by asking questions, providing feedback on encountered problems, suggesting alternative implementations and even developing a solution, and implementing and sharing it with the rest of the students' groups. However, the multitude of introduced concepts, tools, libraries along with the compile, runtime, or emulator errors that can arise in Android hinders student's participation

who find themselves in the process of “making their own project work.” The instructor should be aware of this issue and resolve persistent problems so that students can take on the essence of the delivered material.

Conclusions

The popularity of mobile devices running the Android OS and the bright prospects for mobile application developers in the IT market has raised students’ interest in Android development courses in higher education institutes around the world. However, Android software systems are becoming increasingly complex, and designing relevant courses is not an easy task. In order for an Android development course to be successful, it must combine Android programming with state-of-the-art software engineering content.

In this entry, a short course is introduced aiming at illustrating selected software engineering principles, concepts, and techniques in the context of Android application development. It must be noted that there is no need for an instructor to strictly follow the order, number, and content of the steps analyzed. Based on the students’ prior knowledge and the particular goals of each curriculum, the short course can be modified accordingly. As an example, the course could be extended to a full semester course by adding an introduction to the basics of Android development (e.g., Android components and life cycles, building of views, etc.) as well as additional steps illustrating the use of additional software engineering concepts or more cases of the already examined ones (i.e., more design patterns, metrics, and refactoring types). Another axis along which the course can be extended concerns the functionality of the application itself, which can be turned into a much more complicated one, involving 2D graphics, storage in a database, and communication with a server. However, it should be borne in mind that the essential goal of such a course is not an introduction to Android programming per se, but rather the leveraging of well-established software engineering practices to the benefit of mobile application development.

[Art component of remote training](#); [e-learning](#); [Remote training](#)

The e-learning has started to develop in Russia since the beginning of the 2000s. The e-learning service consumers are as follows:

- Companies that need to systematically provide a large number of seminars devoted to their products and services to a large number of employees. Banks, financial corporations and insurance companies may be referred to as such types of companies, where all of them have rather large and simultaneously constantly changing product lines. In this regard, it is rather impossible to constantly develop and conduct in-person product trainings since it is too expensive and slow.
- Companies with standardized technologies and procedures. They have a library of standard courses, for instance, fire safety courses, or

courses on how to process some documents. These courses usually require minimal changes over a long period of time. Indeed, this approach saves the company's money and staff's time significantly.

- Companies with high turnover of employees, for example, tellers or sellers.
- Companies (including secondary and higher educational institutions) with geographically distributed branch networks. On one hand, the use of remote training products allows for providing the same training regardless of the branch location, and, on the other hand, it allows for saving a large amount of the company's money at the expense of travel costs for teachers and/or employees.

The analysis of the remote training organization experience at the Russian universities has shown that managements of many universities have developed and approved the models and road maps to introduce e-learning into the educational process, and allocated funds for material incentives for teachers. There has been developed and implemented a provision on implementation of e-learning. An additional monthly fee calculation method for teachers working with students through e-courses has been introduced. Parameters like technological course card formation, student e-course access, student e-course enrollment percentage, course grade book completeness, and percentage of students who took part in the education quality questionnaire served as additional monthly fees criteria.

The main difficulties in the e-learning introduction process are as follows:

- Solid belief among the education quality experts that the training efficacy depends solely on introduction of new electronic tools into the learning process.
- Lack of understanding among experienced teachers of what e-learning means. Many of them see e-learning as a dangerous competitor to the traditional learning model. Note that their worries are rather well founded in some cases (depending on the subject features).
- There are some teachers who clearly understand that, with the introduction of new

technologies, they will have to change their formal approach to teaching and authoritarian teacher–student communication style formed during the recent years and therefore resist the student feedback.

- A fairly large group of proactive and, as a rule, younger teachers has emerged who arrange their work with students by means of electronic courses which, however, cannot be considered satisfactory in many cases due to professional insufficiency.
- Low information culture level among employees.
- Poor knowledge of advanced methods and practices.
- Outdated employee motivation system.

For the purposes of legal registration and development impulse, the Russian Law “On Education” has been developed stating that e-learning should be considered an auxiliary tool for the traditional learning process.

Depending on the level of enhancing the learning process with the online content delivery technologies, the nature of interaction among participants and peculiarities of some subjects, the experts distinguish:

- Conventional training (without electronic technologies)
- Conventional web-supported training

The blended training system, which has been considered the highest quality and most promising learning process model worldwide (MIT Open Courseware 2014; Stanford Online 2014; Söderström et al. 2012), still constitutes a terra incognita for the Russian educational system. Russian experts believe that the blended training aimed at reduction of the number of classrooms due to transfer of a part of classes to the electronic environment will extremely impact the quality of professional training. In this sense, the flipped classroom technology is considered unacceptable since its essence is in the rearrangement of the key components of the educational process based on the active use of the electronic learning environment.

The traditional Russian web-based training system requires a teacher who will develop distance learning courses, electronic textbooks, training aids and assessment tools.

In this sense, a great role is played by the creative method of teaching, which, to a large extent, can influence the formation of students' attitudes toward science. Every teacher knows that the student's attitude to the subject, and, hence, to science, may be different. It may cause hate or disgust in some, dislike or indifference in others, or interest, love, and, finally, passion which may then develop into an obsession. In this case, the entire responsibility lies on a teacher almost exclusively, since, beyond any doubt, every subject studied by the listener is forever associated in his/her mind with a person who taught the subject.

However, a teacher, a lecturer, or an artist who is able to captivate listeners and evoke their interest with his/her topic from the other side of a screen is a rarity. We must admit that not many people are endowed with this gift.

There are many teachers who are fluent in the subject matter; they are wonderful researchers, but they absolutely lack any artistic ability. Many lecturers are too static and tense in front of a camera. They lack the freedom of communication that is usually there between the lecturer and the students in the classroom. A teacher who lectures from a monitor screen may be called a speaker in most cases.

Therefore, great attention is given to the quality of the basic element of distance learning – video lectures (Ardowsky 2006; Komarova 2006). The degree of professional preparation will determine the training success. Below are the recommendations for creating a high-quality video product.

Each lecture should be performed enthusiastically. If a teacher finds the lecture boring, then it is ten times more boring to the audience.

The lecture must be created like artwork. It must have a plot, plot development, and denouement despite the fact that the lecture cannot be considered a genuine artwork since it is only a part of the course, its piece. Nevertheless, the lecture must be created based on a certain emotional curve. Emotion is understandable: it is

the mood, which marks the whole lecture. To be more understandable during a lecture, as well as, for example, in a dramatic performance, a certain curve must always be present (e.g., Schiller's dramas are structured in a way that the central action, the maximum emotion is always present in the third act).

Since a lecturer enters the audience knowing his/her first word, he/she should know the last word before leaving the room. The end of the lecture should be thought over carefully just like the beginning.

Great attention should be paid to the direction of the lecture and its rehearsal. The direction of the form begins only after the thought-out content of the lecture, drawn-up emotions, developed drawings, selected examples. The first thing to do is find out what classroom and what blackboard you will use for your lecture. The direction of the text on the board is of great importance: you should know the board size to write the first line, if the board space is enough to provide some drawings, and so on.

A very important thing is the audience entrance plan: how would you enter it, if it is very large, for example?

It is necessary to think in advance about your posture and the words you will say. You should also know how to enter a specific lecture. This will largely determine its color, its tonality. The audience is a very accurate instrument that may reflect the lecturer's mood.

An important point is the direction of your gestures. It is necessary to think in advance whether you could help the audience understand your words using your gestures.

After the plan of directing all your gestures has been thoroughly thought out, it is necessary to think about your voice intonation, which is inextricably linked with the presentation. You should decide which intonation should be in which place of the lecture, where and how you could emphasize it. Intonation is very important since it can even give the audience some rest during the lecture.

Then a lecture rehearsal goes. First of all, a purely formal rehearsal is needed: it is necessary to check if everything you say can be quickly recalled.

After the rehearsal of the lecture contents, a rehearsal of all that has been intended should begin: your intonation, gestures, and so on. Then you need to put your watch on the table and repeat everything over again. This is especially important for the young teachers since they usually do not have a sense of time. The sense of time is one of the qualities that a lecturer needs.

A lecturer should give time to himself/herself and the audience to concentrate and create the necessary mood.

It is necessary to introduce elements of philosophy of a subject into the subject course, as well as historical, biographical information on the major persons into the presentation. Introduction of the elements of history into the training course should be performed in three directions:

- Paul Painlevé wrote, “It is necessary to give students an opportunity of touching the very roots of experimental methods and learn the most skillful techniques created by great researchers—skills and methods that are extremely subject-specific and much more convincing and fruitful than any theorem or rule” (Painlevé 1922).
- Extensive use of the richest historical material during the lectures. For example, the history of every general engineering science is very rich in examples emphasizing its importance to develop the military power of the countries and their equipment in general. Certainly, such examples can significantly increase the interest of students in the subject they study.
- Inclusion of biographies of the creators of certain sciences into the lecture. The pedagogical experience shows that a lively, vivid display of the leading figures in the world science like Galileo, Kepler, Lagrange, Coriolis, Bernoulli, and others helps not only reveal the methods and techniques of the scientific research to the students but also “breathe” that very scientific pathos into the audience, that very passionate attitude toward science which these great scientists were living with.

Summarizing the above, we can draw the following conclusions:

1. It is necessary to create high-quality multimedia applications for distant teachers so that these multimedia applications can be compiled taking into account the teacher’s rich past training experience.
2. A distant lecturer should undergo special artistic training whether it is an advanced training course or some acting technique classes.
3. An alliance between two professionals is also possible where one is a teacher and researcher and the other is a professional artist: the first one develops the course content and the second embodies the idea in front of the camera while both of them do one common thing.

Artificial Intelligence in Education

Wayne Holmes

Institute of Educational Technology, The Open University, Milton Keynes, UK

Synonyms

Adaptive learning; Augmented intelligence in education; Dialogue-based Tutoring systems; Intelligent tutoring systems; Personalised learning

Introduction

Artificial Intelligence (AI) technologies have been researched in educational contexts for more than 30 years (Woolf 1988; Cumming and McDougall 2000; du Boulay 2016). More recently, commercial AI products have also entered the classroom. However, while many assume that Artificial Intelligence in Education (AIED) means students taught by robot teachers, the reality is more prosaic yet still has the potential to be transformative (Holmes et al. 2019). This chapter introduces AIED, an approach that has so far received little mainstream attention, both as a set of technologies and as a field of inquiry. It discusses AIED's AI foundations, its use of models, its possible future, and the human context. It begins with some brief examples of AIED technologies.

The first example, *Cognitive Tutor*, is a type of AIED known as an *intelligent tutoring system* (ITS, which currently are the most common of AIED technologies). It addresses the domain of mathematics for students of primary or secondary school age, and aims to mirror a human tutor by delivering instruction personalized to each individual. *Cognitive Tutor* is also a rare case of an AIED technology that has bridged the gap from university research (at Carnegie Mellon University) to a successful commercial operation (Carnegie Learning (<http://www.carnegielearning.com>)) and is also unusual in having robust independent evidence of its effectiveness (Pane et al. 2014). As individual students work through carefully structured mathematics tasks, the system monitors the student's progress (successes and misconceptions), re-phrases questions, and re-directs the student along more suitable learning pathways and provides individualized feedback (explaining not just why the student got something wrong but also how they can get it right). It achieves all this by combining individual student interaction data with the interaction data of the many thousands of students who have already experienced the system, using that data to learn, adapt, and improve its models of mathematical skills and student learning.

A second quite different AIED example is *MASELTOV* (<http://www.open.ac.uk/iet/main/>

[research-innovation/research-projects/maseltov](http://www.open.ac.uk/iet/main/research-innovation/research-projects/maseltov)), a research project in which AI was used to support language learning by recent migrants to the UK, using devices that many people carry with them all the time – smartphones (Gaved et al. 2014). The *MASELTOV* smartphone app used GPS data and AI techniques to provide context-sensitive and personalized language-learning support. For example, the app was able to detect when a user entered a doctor's surgery or a supermarket, each of which would trigger it to recommend appropriate English resources personalized to the individual's language skills. In the supermarket, the app would provide vocabulary and phrases to help the user find the items that they wanted to buy; in the doctor's surgery, it would provide appropriate words (such as symptoms, parts of the body and diagnoses) together with information about the available health services.

A final brief example comes from China. *Smart Learning Partner*, from Beijing Normal University's Advanced Innovation Center for Future Education, is a mobile app that enables students to connect with tutors using their smartphones. Students can use the app at any time of the day or night to search for a tutor, in order to ask them specific questions about any school topic for which they want some additional support. There are several thousands of tutors available on the app, thanks to local government funding, all of whom have been rated (much like a shopping app or a dating app) by users (in this case, the users are other students). The student chooses their tutor (based on the school topic and the tutor ratings), connects and is given 30 min of free one-to-one online tuition (sharing voice and screens but not video). Although the AI is relatively simple, *Smart Learning Partner* uses it to provide a unique student-centered system that enables students to get exactly the support that they want (rather than the instruction that a system such as an ITS might prescribe). Data from all the interactions are then aggregated and made available to the schools, so that trends in student questions can in a virtuous circle be identified and given more attention in the classroom.

The AI Foundations of AIED

A full understanding of AIED depends on understanding something about AI more generally. The field of AI first emerged from a seminal workshop held at Dartmouth College in the USA as long ago as 1956. Over the following decades, AI developed in fits and starts with periods of rapid progress interspaced with periods, known as *AI winters*, where confidence and funding all but evaporated. Most recently, over the past decade, with the advent of faster computer processors, the availability of large amounts of big data, and the development of new computational approaches, AI has entered a period of renaissance.

Nonetheless, what actually constitutes AI still is often disputed (as is the name itself, with some researchers preferring *augmented* rather than *artificial* intelligence). In fact, for many, as has been suggested earlier, AI is synonymous with humanoid robots, which might be because AI and robots seem to feature together in the news and on television almost every day. In fact, while robotics is a core area of AI research, AI is being used in many different ways and is growing exponentially (while the dystopian images of futuristic robots remain firmly in the realm of science fiction). Paradoxically, though, the more that AI is integrated into our daily lives, the less we think of it as AI:

A lot of cutting edge AI has filtered into general applications, often without being called AI because once something becomes useful enough and common enough, it is not labeled AI anymore (Nick Bostrom, Director of the Future of Humanity Institute, University of Oxford) (<http://edition.cnn.com/2006/TECH/science/07/24/ai.bostrom/index.html>)

Instead, AI is often labeled as a computer program (such as email spam filtering), a mobile phone assistant (such as *Siri*), or perhaps an app (such as *Duolingo*). Nonetheless, many recent developments in AI have been both ground-breaking and transformative. AI techniques such as machine learning, neural networks, evolutionary computation, and supervised, unsupervised, and reinforcement learning have been used in applications as diverse as autonomous vehicles, online

shopping, auto-journalism, online dating, stocks and shares dealing, and legal and financial services.

Automatic face recognition, for example, is one area that has fairly recently made a dramatic leap forward while simultaneously becoming almost invisible in daily life (it is the technology used in smartphone cameras to ensure that faces are always in sharp focus and at e-passport gates to identify travelers before allowing them to enter a country). Face recognition was noticeably improved when, in 2012, Google presented a brain-inspired AI *neural network* comprising 16,000 computer processors with 10 million randomly selected YouTube video thumbnails. By using *deep-learning* techniques, and despite not being told how to recognize anything in particular, this *machine learning* system soon *learned* how to detect human faces in photographs. Two years later, Facebook introduced a nine-layer deep AI *neural network*, involving more than 120 million parameters, to identify (not just detect) faces in timeline photographs. It was trained on a dataset of four million images of faces that had previously been labeled by humans (Facebook users), and achieved an accuracy in excess of 97%, which almost matches human-level performance. However, although impressive, these examples also highlight a key difference between AI and human intelligence: a human does not need to see ten, or even four, million faces before it can recognize a family member, a friend, or a celebrity.

Another area that has seen much AI development is meteorological forecasting, with machine learning being shown to be more accurate at predicting weather than traditional simulation-based forecasting. Meteorologists have long tracked weather data which they enter into complex knowledge-based simulations to make forecasts. However, AI forecasting mines vast amounts of historical weather data, and uses *neural networks* and *deep learning* to identify data patterns (rather than to feed into simulations) in order to make data-based predictions about future weather conditions.

A final brief example is the use of AI in medical diagnosis, with AI techniques being used by radiologists to help them identify anomalies in

medical images more quickly and while making fewer mistakes. For example, one system looks for irregularities in X-ray images and, depending on what it finds, assigns it a priority. If it finds nodules on an image of a pair of lungs, it assigns a high-priority status and sends it to a pulmonary radiologist for further checks.

One thing that all these examples demonstrate is that AI is a highly technical area, which is too complex to explore in depth here (two seminal books that do cover much of AI's complexity are Russell and Norvig 2016; Domingos 2017). In fact, many people involved have advanced degrees in mathematics or physics, although AI is increasingly being offered as a "service" (for example, Google's TensorFlow, IBM's Watson and Microsoft's Azure). Nonetheless, because some have already been mentioned repeatedly and because they play an important role in AIED, some closely interlinked AI topics will be briefly introduced: algorithms, machine learning, deep learning, neural networks, and Bayesian networks. The section then concludes with a brief mention of so-called *General Artificial Intelligence*.

Algorithms

AI often involves talk of *algorithms*, which are simply descriptions of the steps needed to solve problems (ordinary computer programs are really nothing more than lengthy algorithms). It is probably fair to say that Google owes its existence to a single algorithm, PageRank (Fig. 1), which was developed in 1996 by the Google founders at Stanford University. PageRank (apparently named after the Google founder Larry Page rather than web pages) is an algorithm that ranked the relative importance of a website by counting the number and quality of external links to the website's pages, to determine where the website appeared in a Google search.

In fact, the history of AI might be thought of as the history of the development of increasingly sophisticated and increasingly efficient (or elegant) algorithms; while what makes AI algorithms distinct from other software is simply that they are applied to areas we might think of as essentially human (such as visual perception, speech recognition, decision-making, and learning).

Machine Learning

While most computer software (including much early AI) involves writing in advance the exact steps that the software will take, or specifying rules that will be followed exactly, machine learning is about getting computers to act without being given explicit steps or rules. Instead of the algorithms being *programmed* what to do, they have the ability to *learn* what to do. Image and speech recognition, self-driving cars, computational biology (for example, using computers to identify tumors), and digital companions (such as Amazon's Alexa), as well as the Google DeepMind AlphaGo program that beat the world's number one player of Go, have all been made possible thanks to machine learning. In fact, machine learning is so widespread today (almost everyone has experienced some form of machine learning usually without being aware of it) that for some researchers and developers it has become synonymous with AI.

There are three headline approaches to machine learning: supervised, unsupervised, and reinforcement. In **supervised learning**, the AI is first trained with data for which the output is already known. For example, the AI might be trained with many thousands of photographs of people that have already been labeled by humans (this is broadly speaking the approach, mentioned earlier, used by Facebook to *identify* people in photographs). The AI can then be used to label automatically new data (in this example, to

$$\text{PageRank of site} = \sum \frac{\text{PageRank of inbound link}}{\text{Number of links on that page}}$$

Artificial Intelligence in Education, Fig. 1 The PageRank algorithm that played a major role in the early years of Google

identify and label automatically the same Facebook users in new photographs). In **unsupervised learning**, on the other hand, the program is provided with even larger amounts of unlabeled data, which it uses to find patterns that enable it to classify new data (this is broadly the approach, mentioned earlier, used by Google to detect faces in photographs). Finally, in **reinforcement learning** the program is provided with some initial data from which it derives an outcome that is assessed as correct or incorrect, and rewarded accordingly (for example in an AI-driven computer game, the score is increased) or punished (the score is reduced). The program uses this to update itself and then it tries again, thus developing iteratively (evolving) over time.

Neural Networks

Machine learning often uses *neural networks*, so named because they are inspired by how neurons work and are connected in animal brains. However, although AI neural networks have been trained to do some incredible things, they are primitive in comparison to most higher-order animal brains. They usually involve only a few thousand *neurons* (in some exceptional cases, a few million) compared to the human brain, which has around 100 billion neurons and trillions of connections. In any case, AI neural networks comprise several layers of neurons (Fig. 2): typically an input layer (that takes stimuli from the environment), one or more hidden computational layers, and an output layer (that delivers the result of the computation). All the neurons are interconnected, with each connection having a

weighting to determine whether one neuron excites or inhibits the next neuron (again in a process inspired by synapses in animal brains). During the machine learning process, it is these weightings that are adjusted, usually by reinforcement learning, and that allow the AI subsequently to compute outputs for new stimuli. Neural networks have been shown to be particularly effective in many different AI systems, for example, for image recognition (identifying people) and natural language processing.

The hidden layers are key to the power of neural networks but they also bring an important problem. It is not possible (or at the very least it is not easy) to interrogate a neural network to find out how it came up with its solution (for example, how did it identify a particular person or a particular need?). In other words, neural networks can lead to decision-making for which the rationalization is hidden and unknowable, and possibly unjust (O'Neil 2017), a critical issue that is the subject of much research (e.g., Morcos et al. 2018).

Deep Learning

Neural networks comprising multiple hidden layers are known as *deep learning*. This involves automatic iterative analysis that clusters and classifies data and makes predictions. For example, once a deep learning algorithm determines that a picture contains a particular shape, it cycles again to find other shapes, and then cycles again to identify the connections between those shapes, iterating repeatedly until it has recognized what it is looking at (for example, a face). Deep

Artificial Intelligence in Education, Fig. 2 A representation of a typical simple neural network

learning is the headline approach used by *AlphaGo*, to learn how to win at the game of *Go*.

Bayesian Networks

Bayesian networks are a type of statistical model employed by some AI algorithms that enable, in uncertain domains, computational tasks such as prediction, anomaly detection and diagnostics. They combine principles from graph theory, probability theory, and statistics. Drawn graphically, a Bayes net comprises various lines (also known as edges) which intersect at nodes, with the nodes representing variables and the lines representing interdependencies between those variables.

To give a simple example, using a Bayes net approach, an AI system might be designed to predict (calculate the probability of) the flavor of ice-cream that a customer might buy depending on the weather and temperature of the day. Here, the nodes represent the known data (whether it is sunny, whether it is hot, and choices of ice cream flavor made by previous customers) and an uncertain outcome (what ice cream flavor will be chosen today). The Bayes net computation begins with probabilities given in each node that have been derived from training data (comprising records of weather, temperature and customers' choice of ice-cream flavors) to derive the probabilities of various outcomes (the ice-cream flavors that will be chosen by customers in a combination of weather and temperature circumstances). In fact, a typical AI Bayesian network might comprise tens (or hundreds) of variables (nodes) with intricate interdependencies (edges). However, the Bayesian computational approach makes it possible to infer precise probabilities in such complex environments in order to inform usable predictions (to continue with the example, to help the ice-cream seller decide how much of each ice-cream flavor to make).

General Artificial Intelligence

All the examples of AI mentioned so far are domain-specific, which means that they are tightly constrained and very limited. For example, the AI used to win at *Go* cannot play a game of chess, the AI used to predict the weather cannot predict

movements in the stock market, and the AI used to drive a car cannot be used to fly an aeroplane. So-called General Artificial Intelligence, AI that like human intelligence can be used in any circumstances, does not yet exist. And, despite the rapid developments in AI and the concerns expressed by many leading scientists (e.g., Hawkin et al. 2014), it is unlikely to exist for decades (even for leading AI advocates, General AI appears to be due to arrive at some ever-receding future date, usually around 30 years from the time of writing, Müller and Bostrom 2016). In fact, currently, rather than general applications (AI that can be used in any context, Domingos 2017), the focus for most AI research continues to be on domain-specific areas – such as autonomous vehicles, health, weather forecasting and stocks trading, and education.

Introducing AI in Education

AI in education research (AIED) has considered a variety of ways in which AI systems might be used to support both formal and informal learning. It has involved the development of many online tools that aim to support learning while being flexible, inclusive, personalized, engaging, and effective (Holmes et al. 2018). AIED brings together AI and the learning sciences, and thus involves two main complementary strands: developing AI-based tools to support learning and using these tools to help understand learning (how learning happens).

In addition to being the engine behind much “smart” ed tech, AIED is also a powerful tool to open up what is sometimes called the “black box of learning”, giving us deeper, and more fine-grained understandings of how learning actually happens. (Luckin et al. 2016, p. 18)

In other words, AIED research can have an important impact both on classroom tools (such as Cognitive Tutor) and on learning theories applicable in classrooms where there is no AI. For example, by modeling how students go about solving an arithmetic problem and, for example, identifying misconceptions that might have been previously unknown to educators, researchers and teachers can begin to understand much more about the

process of learning itself which can then be applied to classroom practices.

AIED Models

AIED often involves computational *models* (in AI, a model is a highly simplified computational representation of something in the real world, just like a model car is a simplified representation of a real car). In particular, *intelligent tutoring systems* (ITS such as Cognitive Tutor) are often built around three core models: *pedagogy*, *domain*, and *learner*, all of which interact in complex ways and are combined to adapt a sequence of learning activities for each individual student (Fig. 3). A fourth AIED model is the *open learner* model.

The AIED **pedagogy model** represents knowledge about effective teaching and learning approaches that have been elicited from teaching experts (and that constitute the learning sciences). This includes, for example, knowledge of instructional approaches (Bereiter and Scardamalia 1989), productive failure (Kapur 2008), guided discovery learning (Bruner 1961), collaborative learning (Dillenbourg 1999), the zone of proximal development (Vygotsky 1978), deliberate practice (Ericsson et al. 1993), interleaved practice (Rohrer and Taylor 2007), cognitive overload (Mayer and Moreno 2003), formative feedback (Shute 2008), uncertain rewards (Fiorillo 2003), and assessment for learning (Black et al. 2003).

The AIED **domain model**, on the other hand, represents knowledge about the subject that the system aims to help the students learn. This might, for example, be knowledge about mathematical procedures, genetic inheritance, or the causes of World War I. In fact, over the years, mathematics for primary and secondary school students has dominated AIED (mathematics, along with physics and computer science, are AIED's low-hanging fruits because they are, at least at school and undergraduate level, well-structured and clearly delineated), although recent AIED research has investigated AI to support learning in less well-defined areas (such as essay writing across the humanities, Landauer et al. 2009; Whitelock et al. 2015). Finally, the AIED **learner model** represents knowledge about the students (for example, about student interactions, achievements, challenges, misconceptions,

responses, and emotional states while using the system), both for all the students who have used the system so far and for the individual student using the system right now. Figure 3 shows how these three models might be connected in a typical AIED intelligent tutoring system.

In this exemplar architecture, algorithms draw on the pedagogy, domain, and learner models to determine what specific learning activity (for example, some textual content or a collaborative learning activity) should be presented to the individual student and how it should be adapted to that student's needs and capabilities (over time, this means that individual students experience their own unique personalized learning pathways). Then, while the student engages with this adaptive learning activity, the system automatically captures thousands of data points representing each individual interaction, the student's achievements, and any misconceptions that they have demonstrated. Some systems also capture other data such as the student's speech and an indication of their affective (emotional) state.

All of this data is then analyzed (possibly using machine learning or Bayesian network techniques), both to provide the student with individualized formative feedback (to support their learning according to their individual needs) and to update the learner model (to inform the system's next adaptive learning experience). The analysis might also, in some circumstances, update the pedagogy model (with those approaches to pedagogy used by the system that have been shown to support student learning most effectively) and domain models (perhaps with previously unknown but apparently not uncommon misconceptions).

Some AIED ITS also feature a fourth model, the open learner model shown in Fig. 3 (Dimitrova et al. 2007). Open learner models aim to make visible (explicit), for the learners and teachers to inspect, both the teaching and learning that has taken place and the decisions that have been taken by the system (which is especially important if the system uses a neural network approach where, as noted earlier, it can be otherwise difficult to decipher how a decision has been made). This enables learners to monitor their achievements and

Artificial Intelligence in Education, Fig. 3 Flowchart representing a typical AIED intelligent tutoring system architecture, including the pedagogy, domain, learner and open learner models

Artificial Intelligence in Education, Fig. 4 A simplified overview of learning analytics

personal challenges, supporting their metacognition, and enables teachers to better understand each individual learner’s learning (their approach, any misconceptions, and their learning trajectories) in the context of the whole class.

AIED and Learning Analytics

AIED is sometimes linked to another developing field of research in education known as Learning Analytics (LA) or Educational Data Mining (EDM). LA, to focus on just one, involves “the measurement, collection, analysis and reporting of data about learners and their contexts, for purposes of understanding and optimizing learning and the environments in which it occurs” (Siemens 2011). It applies statistical techniques from big data research (Mayer-Schonberger and Cukier 2013) to digital traces in educational contexts. In many ways, there are clear overlaps

between LA and AIED (Figs. 4 and 5). In both LA and AIED, student interaction and outcomes data are analyzed, and the results may be shown in visualizations (for example, in student dashboards). However, although the distinction is becoming increasingly blurred, while LA typically uses the data and analysis to provide insights to inform human intervention (by, for example, teachers), AIED uses the data and analysis to initiate some kind of automatic intervention (such as personalized feedback or learning pathways for students, or automatic student forum post aggregation for teachers).

AIED Applications

There are many AIED-driven applications being used in schools and universities. Here, building on

Artificial Intelligence in Education, Fig. 5 A simplified overview of AIED

the examples mentioned earlier, an illustrative sample is surveyed. As mentioned earlier, the most common types of AIED are so-called *intelligent tutoring systems* (ITS), with Cognitive Tutor being a leading example (for a comprehensive history and discussion of ITS see Woolf 2008). ITS aim to simulate one-to-one (personal) human tutoring, which has long been thought to be the optimum condition for learning, although it is typically costly (at least in terms of teacher time) and so beyond the reach of most students. Famously, Benjamin Bloom (1984) calculated that students receiving personal tuition could achieve outcomes that were two standard deviations (2-sigma) above students taught in conventional classrooms. Although the accuracy of this has recently been challenged (VanLehn 2011), the aim of many ITS researchers has been to devise systems that answer the “‘2-sigma problem’. Can researchers and teachers devise teaching-learning conditions that will enable the majority of students . . . to attain levels of achievement that can at present be reached only under good tutoring conditions?” (Bloom 1984). In fact, VanLehn calculates that the correct figure for human tutoring is closer to 0.8 sigma and that many ITS are already almost as effective (VanLehn 2011).

Three influential examples of personal tutors are *AutoTutor*, *Andes*, and *CIRCSIM*, each of which has been shown to achieve at least 1.0 sigma improvement over conventional classroom teaching. *AutoTutor* was an online system that aimed to “simulate the dialogue patterns of

typical human tutors” in the domain of computing (Graesser et al. 2001). The system’s pedagogy model adopted the principle that it is important “to encourage students to articulate lengthier answers that exhibit deep reasoning rather than deliver short snippets of shallow knowledge” (ibid.), which it addressed by engaging students in a series of written exchanges and by prompting them to elaborate. Meanwhile, feedback mechanisms included providing hints, extending student responses, and correcting misunderstandings. *Andes*, on the other hand, was an ITS focusing on the domain of physics that aimed to replace students’ pencil and paper homework with an interactive and intelligent interface. The system presented students with physics problems for them to solve, each of which usually consisted of many steps (such as drawing vectors, drawing coordinate systems, defining variables and writing equations). After the student completed each step, the system gave feedback, such as hints on what was wrong with an incorrect step or what kind of step to try next. Finally, *CIRCSIM* was a language-based ITS for 1st-year medical students, which was designed to help them learn about the reflex control of blood pressure. It involved one-to-one interactions between the student and the computer, using natural language processing and generation, adopting a pedagogy model that assumes “real understanding of something involves, at least in part, an ability to describe the basic concepts in appropriate language” (Evens and Michael 2006). Accordingly, students were asked to

solve small problems while engaging (similarly to *AutoTutor*) in a Socratic dialog (an iterative conversation of questions and responses) with the computer.

An example alternative to ITS is *iTalk2Learn*, an AIED system for children aged 8–12 years old who are learning fractions, which was designed to detect, analyze and respond to speech in real time in order to improve learning (Rummel et al. 2016). Specifically, the platform supported the robust learning of fractions by providing activities to help develop both *conceptual* and *procedural* knowledge of fractions. Conceptual knowledge is fostered in an exploratory learning environment called *Fractions Lab*, which facilitates students to answer given fractions tasks using virtual manipulatives (graphical representations of fractions) in any way that they choose. Procedural knowledge, on the other hand, is fostered by structured practice activities, in a commercial ITS called *Maths Whizz*. A student's unique sequence of interleaved exploratory and structured practice activities is determined by an overarching intervention model (Mazziotti et al. 2015), the aim being to achieve optimum conditions for learning (avoiding students being under- or over-challenged, which may trigger either boredom or anxiety). Sequencing decisions are made according to the student's level of *challenge* and their *affective state*, both of which are inferred from the student's interaction (what they click and the actions they take on the screen) and their speech (including key words and prosodic features such as “um's” and pauses) and all of which are recorded in the student model. Throughout, the system uses a Bayesian network approach to deliver targeted formative feedback at three levels: *Socratic*, *guidance*, and *didactic* (Holmes et al. 2015). *Socratic* feedback draws on the dialogic approach to teaching (Alexander 2010), which emphasizes the benefits of open questioning to encourage students to consider and verbalize possible solutions. The second level, *guidance*, reminds students of key domain-specific rules and the system's affordances. The third level, *didactic* specifies the next step that needs to be undertaken in order to move forward (this rarely-delivered final feedback also operates as a back-stop, ensuring that the student is not left floundering).

Another example AIED is *OpenEssayist* (Whitelock et al. 2013), which uses Natural Language Processing to provide automated meaningful feedback on draft essays. Unlike earlier AIED systems that were developed to *grade* essays and to *instruct* students how to fix problems (such as Criterion, Burstein and Marcu 2003; Summary Street, Franzke and Streeter 2006; and IntelliMetric, Rudner et al. 2006), *OpenEssayist* encourages the user to reflect on the content of their essay in order to promote self-regulated learning, self-knowledge, and metacognition. It uses linguistic technologies, graphics, animations, and interactive exercises to enable users to reflect on whether the essay adequately conveys the intended meaning and to self-correct before submitting their essay for summative assessment. The system was based on the assumption that the quality and position of key phrases in an essay illustrate how complete and well-structured the essay is, which it determined by means of key phrase extraction, identifying which short phrases are the most suggestive of an essay's content, and extract summarization.

Another use of AI in education is to focus on supporting teachers to support students, rather than on supporting the students directly. One example of this is the *Virtual Teaching Assistant* known as *Jill Watson* (JW), developed at Georgia Tech to address difficulties in providing automatic online assistance for large cohorts of students, particularly in online courses (Goel and Polepeddi 2017). JW was designed to monitor the online forum of a computer science course, to recognize common questions raised by the students, and to provide answers both accurately and quickly. Rather than replacing the human teaching assistants, JW aimed to relieve them of having to respond to low-level questions (such as enquiries about length of assignments, dates for submission, and required readings), which can be both time-consuming and tedious, to allow them to focus on higher-level and thus typically more interesting questions and other teaching activities. JW was originally developed using the IBM Watson AI as a service platform and broadly adopted a supervised learning approach. It was trained with two connected datasets developed over three semesters: the questions that students had asked,

mapped to (labeled with) the answers that the human teaching assistants had provided. Thus trained, the system evaluates new student questions to determine if they can be mapped to question/answer dyads for which the system has confidence (because similar questions have been posed and answered many times). The appropriate answer is then selected and immediately returned to the student. On the other hand, if an appropriate answer cannot be identified with confidence, the question is referred up to a human teaching assistant without introducing any noticeable delay.

Finally, some brief examples involving AIED and two quite different learning approaches: collaborative learning and virtual reality. Research (e.g., Dillenbourg 1999) has shown that collaborative learning, which might involve two or more students undertaking a project together, can be more effective than learning alone. Collaborative learning can, for example, encourage students to articulate their thinking, to resolve differences through constructive dialogue, and to build shared knowledge. However, other research (e.g., Slavin 2010) suggests that collaboration between learners rarely happens without appropriate support. For this reason, various approaches using AI to support collaborative learning have been researched.

AI-driven adaptive group formation, for example, uses knowledge about the participants, most often in learner models, and self-learning algorithms to form a group best suited to a particular collaborative task (perhaps students are all at a similar cognitive level and have similar interests, or they bring different but complementary knowledge and skills) (Mujkanovic et al. 2012). Meanwhile, expert facilitation can involve training systems to support students collaboratively sharing knowledge. For example, Soller et al. (2002) developed a system using Hidden Markov Modeling (another probabilistic technique used in AI) to identify effective and ineffective knowledge sharing between students, so that intelligent guidance might be provided to foster more productive knowledge exchange (while blockchain technologies might enable the fair attribution of credit for individual contributions, Mathews et al. 2017).

Finally, intelligent virtual agents might mediate online student interaction, or simply contribute to the dialogues by acting as a coach, a virtual peer, or a teachable agent (i.e., a virtual peer that the participants might themselves teach). For example, Goodman et al. (2005) developed an agent that interacted with the participants when it detected something happening that was interfering with the learning (such as a student's confusion about a problem or a participant who is dominating the discussion or not interacting productively with other participants).

Virtual reality (VR) and augmented reality (AR) enhanced with AI are both being promoted as having potential for learning. VR can provide authentic experiences that, using VR headsets, headphones, and controllers, simulate in immersive 4D (the three dimensions of space plus sound or haptics) a small part of the real world to which the user would not otherwise have access. These include places such as dangerous environments (like the interior of a volcano) or somewhere geographically or historically inaccessible (such as a black hole or the Cretaceous Period). However, while some (e.g., Hassani et al. 2013) have suggested that learning in virtual realities can enable the student to better transfer that learning to the real world (transfer of learning has long been known to be a problem), and there are examples of VR being used to support medical training (e.g., Ruthenbeck and Reynolds 2015), in a review of VR in K-12 education, Freina and Ott (2015) were unable to find any robust learning outcomes.

Augmented Reality adopts a different approach. Instead of providing an alternative reality, AR overlays rich media (virtual objects such as text, still images, video clips, 3D models, and animations) onto live video images of the existing reality, by means of the cameras and screens on smartphones and tablet devices, in such a way that users perceive the virtual objects as if they are coexisting with the real-world environment. There are many examples. AR techniques can be used to show textual information about a specific mountain (such as its name and maximum elevation) when a smartphone's camera is pointed at it (<https://www.peakfinder.org/mobile>); while another AR app has been

developed, for use in a university science course, that allows the user to view and interact with an anatomically correct 3D model of a human heart. (<https://appstore.open.ac.uk/humanheart>) Nevertheless, despite the promise, again there is currently little evidence that AR leads to any notable learning gains (Bower et al. 2014; Radu 2014).

The Future of AIED

As is clear from both media and this brief review, AI and AIED are rapidly developing areas of research and development. In particular, AIED applications that yesterday seemed fanciful, today are being widely used by students, independently or in schools and universities. Future possibilities are limited only by the imagination and are thus difficult to predict. Here, therefore, briefly surveying four areas in which AIED has substantial potential (building on Luckin et al. 2016) will have to suffice.

Twenty-First-Century Skills

What have been called *twenty-first-century skills* have repeatedly been identified as essential for future students, future work, and future economies (e.g., World Economic Forum and The Boston Consulting Group 2016). These skills include competencies such as critical thinking, problem-solving, creativity, communication, and collaboration, together with character qualities such as curiosity, persistence, adaptability, leadership, social and cultural awareness, and initiative. However, although these essential skills and character qualities may be important, it is unclear how they might best be developed or supported.

AIED might help enhance students' twenty-first-century skills by providing dynamic tools that iteratively improve. For example, while students engage in collaborative problem solving activities in a particular context, the tools might monitor student actions (Who is interacting with the available learning resources and how?), eye contact (What are learners focusing on at any particular time?) and dialogue between groups of students (Who is saying what and to whom?). Over time, it will be possible to identify indicators of the most effective collaborative problem solving strategies, so that students might be guided

(perhaps through automated feedback) in those directions. Monitoring and analyzing dialogue might also be used to connect students engaged in similar conversations, either on opposite sides of the room or in different countries, helping to build AIED-supported communities of practice. Meanwhile, the impact of the context may be further accommodated by means of an additional model built into the AIED system, which might help identify how the combinations of technology, teachers, and environment might be adjusted to improve teaching (Luckin 2010).

Twenty-First-Century Assessment

AIED technologies also have the potential to replace the *stop and test* approach to assessment, as exemplified in examinations. It is well-known that teaching-to-the-test, an inevitable consequence of examinations, impoverishes learning. In any case, exams (for which there is little evidence of efficacy or validity) can only assess a fraction of what has been learned and so provide only a partial picture of a student's capabilities. Exams can also be the cause of serious anxiety for many students.

AIED techniques could, on the other hand, provide continuous formative assessment and just-in-time feedback about learner successes, challenges, and needs that can then be used to shape the learning experience itself (c.f., Foltz 2014). For example, AIED could monitor changes in learner confidence and motivation as they achieve competencies in a new language or in a new topic in geography or history. Alternatively, AIED-driven *stealth* assessments (Shute 2011) could be built into meaningful learning activities, for example, in digital games-based learning or collaborative projects. This might involve continuously monitoring the various indicators of learning, accrediting, and recording the learning as it happens (perhaps in blockchain-secured robust e-portfolios, Sharples and Domingue 2016), and automatically providing guidance on appropriate next learning steps.

Twenty-First-Century Learning Partners

Finally, AIED also has the potential to build artificial *learning companions* that might accompany

and support individual learners throughout their lives. These lifelong learning companions could be accessible via speech on smartphones (and on other smart devices such as Alexa, Siri, or Google Home), and could provide an easy-to-access record of a student's individual learning experiences, successes, and challenges, together with suggestions and ongoing guidance for future study. They might also connect just-in-time with other specialist AIED systems, or with humans who have expertise in particular subject areas (building on the approach used by the *Smart Learning Partner* from Beijing mentioned earlier). Inevitably, at first there will be objections, that learning companions discourage the students from learning the classroom knowledge that has traditionally been deemed to be important. However, in time, as the learning companions enable and support students to make novel connections between learning objects and learning domains that otherwise would have been difficult if not impossible, helping them to build upon and enhance their learning wherever it happens, and as the learning companions become commonplace, perhaps their value will eventually be accepted (in much the same way that calculators are finally becoming accepted in classrooms, Hodgen et al. 2018). Similar AIED could also be used to develop AI teaching assistants, designed to support teachers in their day-to-day work, removing some of the drudgery of teaching and allowing them to focus on the more human aspects of learning.

The Ethics of AIED

No discussion of AI in education can be complete without some consideration of the ethical implications. Yet, while the range of AI technologies being introduced in schools and universities around the world are extensive and growing, the ethics are rarely investigated. There has been work around the ethics of AI in general (e.g., Bostrom and Yudkowsky 2014) and around the ethics of Learning Analytics (e.g., Slade and Prinsloo 2013). However, at the time of writing,

around the world, virtually no research has been undertaken, no guidelines have been provided, no policies have been developed, and no regulations have been enacted to address the specific ethical issues raised by AIED. In short, researchers and developers in AIED are proceeding without any fully worked out ethical groundings, such that it might be argued that all AIED technologies, including those that have been introduced in this chapter, exist in a moral vacuum.

In fact, although perhaps not as newsworthy as robots or self-driving cars, the use of artificial intelligence techniques (such as neural networks, machine learning and Bayes nets) in education has profound implications for students (their skills, knowledge and developing minds) and thus for wider society. In parallel, this also raises an indeterminate number of as yet unanswered ethical questions. To begin with, concerns exist about the large volumes of data collected to support AIED (such as the recording of student competencies, emotions, strategies, and misconceptions). Who owns and who is able to access this data; what are the privacy concerns; how should the data be analyzed, interpreted, and shared; and who should be considered responsible if something goes wrong? For these questions, AIED might usefully draw on the work that investigates the ethics of Learning Analytics (e.g., Slade and Prinsloo 2013). However, while data raises major ethical concerns for the field of AIED, AIED ethics cannot be reduced to questions about data. Other major ethical concerns include the potential for bias (conscious or unconscious) incorporated into AIED algorithms and impacting negatively on the civil rights of individual students (in terms of gender, age, race, social status, income inequality. . .). For these questions, AIED might usefully draw on the work that investigates the ethics of AI in general (e.g., Caliskan et al. 2017). But the AIED ethical concerns centered on data and bias are the “known unknowns.” What about the “unknown unknowns,” the ethical issues raised by and specific to the field of AIED that have yet to be even identified?

One approach is to consider ethical issues in terms of the three main AIED models introduced earlier. At the pedagogical level, the impact of

AIED on pedagogical relationships and how best they can be supported first needs to be addressed. For example, what kinds of AIED interventions are ethically warranted, what kinds of information should be used to justify an AIED intervention, and what kinds of behavioral changes is AIED intended to bring about? At the domain level, it is important to consider how the adaptation of particular subject content amenable to AIED influences the learner experience and their understanding of that content. Finally, at the level of individual learners, issues center on the use of personal information. In addition to the use of learning analytics to profile learners, these include issues around surveillance and covert data collection (involving cutting edge technologies that are poised to collect ever more personal information), and the tension between paternalistic systems and the autonomy of the learner.

Specific AIED ethical questions include: What are the criteria for ethically acceptable AIED? How does the transient nature of student goals, interests, and emotions impact on the ethics of AIED? What are the AIED ethical obligations of private organizations (developers of AIED products) and public authorities (schools and universities involved in AIED research)? How might schools, students, and teachers opt out from, or challenge, how they are represented in large datasets? And, what are the ethical implications of not being able to easily interrogate how AIED deep decisions (using multi-level neural networks) are made?

Strategies are also needed for risk amelioration, since AI algorithms are vulnerable to hacking and manipulation. Where AIED interventions target behavioral change (such as by “nudging” individuals towards a particular course of action), the entire sequence of AIED enhanced pedagogical activity also needs to be ethically warranted. And finally, it is important to recognize another perspective on AIED ethical questions: in each instance, the ethical cost of *inaction* and *failure to innovate* must be balanced against the potential for AIED innovation to result in real benefits for learners, educators, and educational institutions.

Access; Active aging; Computer-based communications; Health information; Internet

Introduction

Aging is emerging as an issue since both the proportion and absolute number of older people in populations around the world are dramatically increasing (WHO 2015). With advances in medicine helping more people to live longer lives, the number of people over the age of 60 years is expected to double by 2050; global life

expectancy has increased by 5 years since 2000 (Gulland 2016) and is expected to increase in industrialized countries. With societies aiming to provide an active aging context for the elderly, a fourth age challenge is emerging. In this context, in addition to the importance of considering the views and needs of the eldest, it is also pertinent that their continuous participation in social, economic, cultural, and spiritual dimension opportunities, together with the promotion of healthy physical development, is ensured.

Assisting elderly non-computer-literate people with, and in the familiar/friendly use of, computer-based communications and Internet access answers a challenge of today's society. Through collaboration between aging and active people and bearing in mind the potential of information and communication technology, it is possible to ensure basic rights to well-being, thus contributing to a better culture of old age (Baltes and Smith 2003). This acknowledges older people's continuing aspirations to well-being and respect (WHO 2015). In a context of progressive Internet societal omnipresence, many believe that if offline older citizens remain offline, they will become increasingly disadvantaged from a socio-ecological point of view. Encouraging older adults' use of information and communication technologies (ICTs) is essential for the creation of bona fide information societies (Selwyn et al. 2003).

Computer-Mediated Communication and Digital Technology Development

With the digital revolution, in the digital era, all entities, collectively or individually considered, are connected to each other, anytime and anywhere, through ubiquitous and pervasive computing. Wireless and mobile technologies, sensing devices, and virtual and augmented reality applications are examples of available technology that has an impact in societies and in the lives of everyone. The complementarity of the Internet of Things, consisting of intelligent and self-configuring nodes interconnected in a dynamic and global network infrastructure, and of cloud computing, which makes real virtually limitless

storage and on-demand processing power (Botta et al. 2016), enables a varied and large number of application scenarios.

Nowadays, computer-mediated communication and digital technologies are increasingly ubiquitous, easily available, and, most of them, user-friendly. Being able to use a digital tool or an application is being facilitated by a number of institutions and structures in societies, via international, regional, and national programs, sometimes through social and educational activities where, despite any initial negative attitudes, success in training is more a function of a proper training program than participants' attitudes (Mitzner et al. 2016).

Adoption and Use of Computer-Mediated Communication by the Elderly

Elderly people are users of computer-mediated communication for a variety of purposes, such as seeking general information, accessing health documentation, and managing health issues, shopping, banking, or online learning. Further to these kinds of pragmatic uses, computer-mediated communication and the Internet may have a role in reducing social isolation and in promoting interconnectedness and social stimulation; information and communication technology, in general, may offer intelligent and supportive living environments that support older people's cognitive and physical problems (Nugent 2007). Despite concerns that some of these technologies also have the potential to restrict freedom of movement and intrude into privacy (Bennett et al. 2017), research also shows that Internet usage by healthy older adults is a safe activity (Karin and Martin 2013). Published research clearly shows evidence that technology, in general, and more specifically computer-mediated communication, can play a relevant role in assisting the elderly: (i) if introduced with foresight and careful guidelines, robots and robotic technology can improve the lives of the elderly, reducing their dependence and creating more opportunities for social interaction (Sharkey and Sharkey 2012); (ii) information and communications technologies

may, to some extent, play an instrumental role in interconnectedness and social stimulation, between the elderly and their families (Bobillier Chaumon et al. 2014); and (iii) in long-term care institutions, the Internet may become an important window to the community (Seifert et al. 2017).

Research and Policy

Research through a systematic review by Peek et al. (2014) shows that technology that enhances safety or provides social interaction is influenced by multiple factors; its authors called for further research to determine if and how the factors are interrelated and how they relate to existing models of technology acceptance. Knowing and understanding how to assist non-computer-literate elderly with computer-based communications is an established field of research, where it has been noted that higher levels of Internet use may be significant predictors of higher levels of social support, reduced loneliness, and better life satisfaction and psychological well-being among older adults (Heo et al. 2015). However, the impact of the Internet on the well-being of the elderly may well be complex (Mellor et al. 2008) and requires continuous research. As stated by Wagner et al. (2010), computer use by older adults is a multidisciplinary topic by nature, requiring research through different methodologies, operationalizations, constructs, or relationships from different disciplines.

In addition to research, the wider community should ensure adequate policy that provides the non-computer-literate elderly with proper state-of-the-art assistive technology and personalized and knowledgeable assistance. Programs and initiatives that may take place can be illustrated by case studies already conducted and published: (i) Patrício and Osório (2016) showed that intergenerational learning with information and communication technology (ICT) contributes to the digital literacy of adults and seniors and fosters lifelong learning, active aging, and understanding and solidarity among generations; (ii) Horwitz and Huss (2016) studied online cultural products as a mediating element for communication between youth and elders; (iii) Brites-Pereira

et al. (2017) are studying how the elderly learn to use digital technologies of movement detection, in a context of developing active aging.

In addition to challenging strategies, such as intergenerational learning, and rich cultural content stimuli, programs and policies need to comply with a multitude of conditions (Larsson et al. 2013), and providers may ponder the enjoyment benefit of the Internet (Lee et al. 2014). Furthermore, for digital seniors, ICT use is not a binary choice because they want to have the flexibility to select for themselves under what circumstances and for what purposes the use of ICTs is appropriate (Quan-Haase et al. 2016).

Listening to the voices of people who have learnt through a whole life will certainly be helpful to assist the elderly not only in computer-mediated communication literacy but also in the adoption of a lifelong learning paradigm.

In summary, a fourth age is emerging, in which assisting the elderly in the use of computer-based communications answers a challenge of today's society. Nowadays, computer-mediated communication and digital technologies are increasingly ubiquitous, easily available, and (for the most of them) user-friendly; in addition, research shows that technology can play a relevant role in assisting the elderly. Therefore, assisting the elderly in using computer-mediated communications not only provides the discovery of new knowledge but also contributes to an active meaningful and dignified aging.

Introduction

Technologies assist individuals who are deaf or hard of hearing (DHH) with access to spoken

information in classrooms, at work, and in primarily social situations; technologies also help individuals who are DHH share information with hearing individuals. These technologies make it possible for individuals who are DHH to participate effectively in activities, when it would not otherwise be possible, such as by providing captions so that individuals who are DHH can follow television programs. Some of these technologies provide information visually, and others enhance auditory information (Gallaudet 2014). Technologies that assist individuals who are DHH may have a feature, such as captions, which is specially designed for them, or may be intended for a wide range of individuals and also meet the needs of individuals who are DHH in certain situations such as the use of networked messaging to facilitate communication between individuals who are DHH and individuals who are hearing (Gray 2008; Gray et al. 2011).

This entry will consider the following five types of technologies that facilitate communication, learning, and participation of DHH individuals:

1. Assistive listening devices (ALDs) that facilitate the access of individuals who are DHH to auditory signals by improving the loudness or clarity of the signal.
2. Captioning technologies that provide individuals who are DHH access to spoken information in classrooms, to television programs and web material, and to phone conversations.
3. Text messaging technologies that enable synchronous (simultaneous) and asynchronous (nonsimultaneous) text communication between individuals who are DHH and individuals who are hearing, often in situations where an interpreter is not available to facilitate communication.
4. Video streaming technologies that make possible remote conversations between individuals who use a sign language.
5. Alarm and alerting devices that help individuals who are DHH with numerous functions in everyday life, such as answering the doorbell; these technologies also operate as signal alerts, such as for catastrophic weather.

Factors that Affect Use of Technology

Before considering these five sets of technologies, the following discussion briefly summarizes three issues that have implications for the nature and effectiveness of technology used with individuals who are DHH: (a) education and work settings, (b) language and academic skills of DHH individuals, and (c) trends in technology.

Educational and Work Settings

With respect to education, virtually all students who are DHH are educated in two types of classrooms, special and general education (mainstream). Special classes typically have a teacher of the deaf, and communication tends to be in a sign language. Communication is more accessible to students who are DHH because if they are in that setting, the teacher regulates the flow of communication and adjusts to the children's communication needs so that the students can understand (Stinson and Kluwin 2011). General education classes are those with primarily hearing students and a regular teacher. Typically, only one student who is DHH (or only a few) is placed into any particular general education class. In these classes, the teacher and students almost always use a spoken language (e.g., English, Greek), and the students who are DHH in these classes usually have difficulty understanding at least some of this communication, unless they receive special services to support communication access and learning. A somewhat similar type of distinction occurs when individuals who are DHH enter the work world. These individuals may work in positions with primarily hearing co-employees, and thus there is often a need for technology that can help individuals who are DHH have access to the spoken communication of hearing employees. A good, but relatively small, number of employees who are DHH work in settings where most employees know a sign language (such as in a school for the deaf), and for them much communication with fellow employees is through a sign language (Kelly et al. 2016).

Communication Characteristics

Two characteristics of individuals who are DHH that affect learning and employment are limited proficiency in reading and writing (Qi and Mitchell 2012; Nikolarazi et al. 2013) and considerable diversity in communication characteristics (Knoors and Hermans 2010). Students who are DHH vary in the knowledge, understanding and use of a sign or a spoken language, and proficiency in reading and writing. These variations relate to the extent that students are placed in general education or special education classes, as well as the nature of accommodations that a student may request, including provision of a sign language interpreter or real-time captioning (Knoors and Hermans 2010; Stinson and Kluwin 2011).

Five Assistive Technologies

Assistive Listening Devices

Language development in a spoken language among individuals who are DHH is associated with the use of the proper listening devices and the benefit that this device provides (Ambrose et al. 2014). In addition to the personal listening device, either hearing aids or cochlear implant, assistive listening devices can improve the quality, audibility, and clarity of the speech signal. In many listening environments, the signal-to-noise ratio (SNR) is very low, that is, that the level of signal (i.e., teacher) is lower than the level of the background noise. This prevents speech perception for an individual, particularly a child, with functional hearing, who needs the signal to be louder than the background noise. The use of assistive listening devices (ALDs) can facilitate the detection of the sound and improve SNR by minimizing background noise, the distance between the sound source and listener, and reverberation (Hinman et al. 2003; Kim and Kim 2014; Dillon 2012; Zanin and Rance 2016).

The most common assistive listening devices include the soundfield amplification systems, the frequency modulated (FM) radio systems, the infrared (IR) transmission, and the magnetic

induction loop. The soundfield systems include a wireless microphone and wireless receiver/amplifier that powers loudspeakers that are placed around the classroom, often on the walls. These speakers are linked to a control center, which can transmit sound from various devices – for example, a microphone worn by a person speaking, a music system, or a whiteboard. The portable systems can be moved around to wherever they are most needed. In rooms with poor acoustics, soundfield systems might be of less benefit because they increase the loudness of the speech signal as well as reverberation. Therefore, the ideal is to use a soundfield system in a classroom with good acoustics. Also, a pass-around microphone is often important because it can amplify the voice of other speakers (i.e., classmates) who might make comments and ask questions (Aussie Deaf Kids 2015; Dillon 2012; Hinman et al. 2003; Inglehart 2002; NDCS 2017; Zanin and Rance 2016).

Additional ALDs include the FM and the IR systems which are both wireless systems that consist of two units, a portable receiver for the listener and a microphone transmitter for the speaker. FM systems use radio waves, while IR systems use light waves. Radio waves travel through the walls, and therefore FM systems in nearby rooms must use different channels. In the case of IR, there are no such issues because walls are opaque to light. Another ALD is the induction loop system which uses an electromagnetic field to carry the sound to the user's ears with or without a personal listening assistive device. In this system, a loop of insulated wire, which might be worn around the neck or might encircle an entire room, is connected to a power source, an amplifier, and a microphone. An amplifier transmits the electrical signal from the microphone to the wire, and this electrical current creates an electromagnetic field that is picked up by the hearing aids or the cochlear implants with a telecoil feature. The users sitting within the loop system can pick up the speaker's voice or TV without distortion and no background noise. The loop is fully adaptable to television, radio, stereo, and tape recorder (Aussie Deaf

Kids 2015; Dillon 2012; Hinman et al. 2003; Inglehart 2002; NDCS 2017a, b; Zanin and Rance 2016).

Further, ALDs are digital transmission technologies that use increased audio bandwidth (up to 7300 Hz) and frequency-hopping to prevent electromagnetic interference and therefore improve the SNR for the listener (Wolfe et al. 2013). Finally, Bluetooth technology allows two electronic devices such as a cell phone, a computer, the TV on one hand, and a hearing aid or a cochlear implant on the other to connect to each other (Hinman et al. 2003; De Raeve 2015).

Captioning

Three types of captioning that individuals who are DHH use are real-time captioning in classrooms, television captioning, and captioned telephones.

Real-time captioning in the classroom. Real-time captioning meets the communication access needs of some DHH students in classes with primarily hearing students. The provider of the service, who is often in the classroom next to the student(s) who are DHH, produces text as it is being spoken by the teacher or other students and displays it on a portable device so that the student can access instruction and, more generally, understand what is taking place in the classroom. In the two common real-time captioning options, the provider uses either a standard typing (QWERTY) keyboard with computerized word abbreviation expansion or a stenographic (stenotype) machine. A little used option, with greater promise for the future, is automatic speech recognition (Ruan et al. 2016; Stinson et al. 2008). The typing-based services often include a messaging feature so that student users, who are unable or uncomfortable using their voice, can ask questions or make comments by typing a message that the service provider can view and read aloud to the class.

Real-time captioning services may be provided in the classroom or remotely. If remotely, the speaker, such as a teacher, typically wears a Bluetooth microphone, and the spoken

message is delivered using either a cellular phone or Voice over Internet Protocol (VoIP) via a cellular or broadband Internet connection (i.e., Skype, Google Hangout). These services also support display of text on diverse devices (standard laptops, smartphones, etc.). Display of the text may be based on an easily downloadable app that runs on iOS and Android devices. To use the service, the user simply connects and then begins to use the service. Some services use a web browser for display of captions. Real-time captioning services usually distribute notes, or saved text, to students after classes (Cawthon et al. 2013; Stinson et al. 2014a). Notes produced by real-time captioning service and a note taker are different from each other. Notes produced with captioning are the saved transcript of the lecture, which may or may not be modified by condensing, bulleting, etc. Compared to this text, handwritten notes involve more rephrasing of concepts and greater condensing.

Real-time captioning is frequently a desirable option for students who are DHH because it helps them understand and learn classroom material by providing information that is permanent and distributing notes (saved text) that contain the actual vocabulary used by a teacher. Also, it helps them deal with the multiple visual demands of the classroom. Based on studies that compared real-time captioning with other services, the students learn the same amount or more with real-time captioning as with interpreting (Marschark et al. 2006; Stinson et al. 2009). Also, sometimes, students rate their understanding of the instructor higher when they receive this service than when they receive interpreting (Stinson et al. 2017a).

Television captioning. Television exerts a substantial influence upon children's learning and socialization. 85% of more than 50 million children in the United States watch television everyday (National Captioning Institute 1983). Children who are DHH watch television as often as children who are hearing do (Lewis and Jackson 2001; Liss and Price 1981). Today, television programs may be viewed with captions. These captions are a text display of the audio component of the television program, which is generally

displayed at the bottom of the television screen (Lewis and Jackson 2001). In order to see these captions, which are generally transmitted in closed format, the viewer must set the caption decoder, which is contained in virtually all television sets, so that it displays captions. A major reason for production of captions is to provide individuals who are DHH access to the audio component of the program. Open captions can be distinguished from closed captions. Open captions are displayed to all individuals who view the video. Closed captions are only viewed when the caption decoder is set to display captions on the screen.

Despite the barriers that individuals who are DHH face in becoming a proficient reader, research has indicated that captions are beneficial to them (Qi and Mitchell 2012). This is consistent with the regular use of various forms of printed information by individuals who are DHH (Stinson 2010).

Researchers have attempted to identify ways of increasing the comprehension of captions by individuals who are DHH, but research to date does not clearly indicate that factors that might be expected to facilitate comprehension, such as caption rate and linguistic complexity, consistently increase comprehension. Reading proficiency has been found to affect comprehension of captions (Braverman and Hertzog 1980; Burnham et al. 2008).

Captioned telephone. Telecommunications relay services allow persons who are deaf, hard of hearing, and deaf-blind or who have speech disabilities to place and receive telephone calls. A communication assistant relays the call back and forth between the person with a disability and the other party to the call. There are different variations in how the service may work. In one option, Internet Protocol-Captioned Telephone Service (IP-CTS), persons with hearing loss are able to almost simultaneously hear and read the communication from the person with whom they are having a telephone conversation. The communication assistant listens to what the party being called says and produces text, such as with a stenotype machine or through re-speaking with automatic speech recognition that automatically

transcribes these words, with the words reappearing nearly simultaneously after they are being spoken by the other party.

Through text-to-voice telecommunications relay services, an individual who is DHH communicates in text what she/he wishes to communicate to the other party, and the assistant repeats in voice what the user has typed and types for the user who is DHH the hearing telephone user's response. Users who are DHH may view telephone captions through a special phone that displays captions, through a downloadable application on a mobile device or a website. These services are often delivered via the Internet. Some countries that provide this service also tend to support it with a small surcharge on users of telephone services (FCC 2017; Power et al. 2007).

This service can enable individuals who are DHH to more effectively use a telephone at their home or jobs. Individuals who use a form of captioned telephone, as opposed to video relay service with a signing interpreter, tend to be individuals who are DHH with relatively good proficiency in their native spoken language (e.g., English), such as those with an acquired hearing loss. When these individuals prefer to communicate by speaking and have enough residual hearing to at least partly be able to follow the conversation of the other party on the phone, they are likely to value using the IP-CTS service (MITRE 2016).

Currently, just more than half of the users of telephones who are DHH are satisfied with use of the phone with the assistance of their hearing aids (MITRE 2016; Payton et al. 2017). In addition, these users report that hearing aids provide on average only 55% benefit during phone conversation (Kochkin 2013).

Text Messaging to Facilitate Communication in Small Groups

A new area of work is an accommodation to facilitate communication between individuals who are DHH and individuals who are hearing in small groups who work together on a task.

These small group situations are quite common. At school, cooperative learning and collaboration learning promote deep, meaningful learning (Cohen 2002; Esmonde 2009; Lunetta et al. 2007; Pintrich et al. 1993; Schuell 1996). However, the benefits of collaboration in school are only possible when students successfully exchange ideas, comments, and insights. Students who are DHH often face communication challenges because the provided services are not adequate for the situation. Furthermore, even in classes where there is a range of services such as professional sign language interpreters, real-time captioning, and note takers, if more than one individual who is DHH attends this class and they participate in more than one group, there may not be enough interpreters to support each of these students. Often mobile devices can help communication in small groups with students who are DHH and students who are hearing. A technology that produces typing or drawing for all group members to see can help level the playing field when DHH students participate. Because typing and drawing are visual and remain visible longer than speech or sign, these are reliable forms of communication.

This text-based communication may be face-to-face or online. The use of messaging and shared documents, such as in Google Docs, has emerged with the growth of wireless Internet services and widespread use of mobile devices. Messaging applications, such as iMessage, may enable participants to more easily communicate with each other longer, relatively complex statements compared to using paper and pencil, gesture, pointing, etc. This form of communication is more likely to occur when a sign language interpreter is not available, when hearing participants do not know sign language, when the DHH participants cannot readily understand spoken communication of the hearing participants through speech-reading and residual hearing, and/or when the DHH individual's speech is unintelligible. A new way for hearing participants in groups to produce messages is through automatic speech recognition. Hearing users voice into a Smartphone, a tablet computer, etc., and the automatic speech recognition engine converts

their spoken messages into print for viewing by all participants with devices networked to share the conversation (Stinson et al. 2017b).

An experimental study of the effect of an iMessage intervention in a situation where two of the participants were DHH and two were hearing provided evidence of the effectiveness of technology in facilitating communication between DHH and hearing individuals in small groups. Results indicated that when iMessage was available, the two students who were DHH stopped signing, the two students who were hearing stopped talking to each other, and everyone, instead, communicated primarily with the whole group through the technology (Stinson et al. 2014b). In addition, research has found that students who are DHH are now increasingly using technology, such as cell phones and laptops, to communicate with students who are hearing in small groups (Stinson et al. 2014b, 2017b).

Video Streaming Communication Technologies

Video streaming technologies allow individuals who are DHH who use a sign language to communicate with other individuals who are DHH and with individuals who are hearing and use sign language over the Internet through video chat and through video relay services.

Online video communication technologies. Video chat, where the participants simultaneously communicate via sign and/or voice over the Internet is a technology that individuals who are DHH often use with each other or with a hearing individual. Examples of video chat include Google Hangout, Skype, and FaceTime. Some educational programs use this technology for an individual with expertise in a field to provide tutoring to a student who is DHH (Elliot et al. 2013). Video chat may be supplemented with simultaneous sharing of photos and documents. When video chat is used for tutoring, it may use virtual whiteboards such as Conceptboard to share this information. For example, in tutoring in mathematics, tutor and tutee may exchange written board work related to solving the problem

by using Conceptboard, or alternatively they may focus their web camera on the mathematical notation that they handwrote on their own whiteboards or paper. Individuals that are using video chat may sometimes switch to using text messaging, such as when there are technical issues with the video (CAT 2015; Elliot et al. 2013). An advantage of the Google Hangouts software application relative to other video chat programs is that it allows multi-platform communication (e.g., video feed, document sharing). Individuals who wish to communicate by sign with each other use video chat to communicate with each other for a variety of purposes, such as for social communication, in addition to using this technology for education.

The idea of using video chat for education of students who are DHH is quite new. The limited evidence to date indicates that this approach is usable and effective and that online tutoring with signing may work as effectively as face-to-face tutoring with signing in assisting students who are DHH (Elliot et al. 2013; Lissaman et al. 2009; Richardson 2009).

Video relay services. Video relay services (VRS) are implemented with the goal to ensure effective phone communication between signing deaf persons and hearing persons. Furthermore, video relay services are provided to enable individuals who are DHH and individuals who are deaf-blind make telephone calls with hearing individuals that function as well as the phone calls between individuals who are hearing and communicate though speech. While captioned phone services are used by individuals who are DHH and who want to use captions to help access the spoken communication over a phone, video relay services are used by individuals who are DHH and who communicate via a sign language. Video relay services use video streaming technology so that the individual who is DHH is able to view a communication assistant who signs the spoken message produced by the hearing individual that the DHH person has called; in addition, the video technology enables the communication assistant to view the signing of the DHH individual so that the assistant can relay the DHH person's signed message to the hearing party on

the phone. The typical VRS communication sequence consists of (a) the user who is DHH signing a message to the VRS communication assistant, (b) the communication assistant relaying this message to the hearing user participating in the phone conversation by converting it into a spoken message, (c) the hearing user replying to the message produced by the user who is DHH with speech, and (d) the communication assistant relaying this message to the user who is DHH by converting it into a signed message. Both the individual who is DHH and the communication assistant use specific software on a computer and a computer web cam to enable this communication (FCC 2017; MITRE 2016; Power et al. 2007). Some countries offer these services through a small charge that is included in the telephone service charge of all of the users of phones in a country. These services are important for enabling persons who are DHH to make all the kinds of phone calls that hearing individuals make: e.g., for work, medical services (appointments), shopping, communication with friends and family, etc.

The limited research and experience in provision of services indicates that while individuals who are DHH, who are primarily users of a sign language, benefit from video relay services and that these individuals prefer video relay to a text-based telecommunication service, video relay lags behind technological advances, and it is not at a level that satisfactorily meets the needs of users who are DHH (MITRE 2016; Steinberg et al. 2006).

Alarm and Alerting Devices

A wide range of alerting or alarm devices are available with a number of features that may help individuals who are DHH to wake up, keep track of time, and be notified of various happenings. Sometimes these devices can inform or alert individuals who are DHH of quite risky happenings, such as incoming weather that is potentially dangerous. An alarm device might have various features such as adjustable volume, vibrating pads, display screen size, flashing

lights, or a combination of these features. Also, the alarm device might sit on a table or be portable. Furthermore, alarm systems may be connected to various household devices such as doorbells, smoke alarm, kitchen timers, and telephone alerts. In addition, instead of using separate notification devices, such as an alarm clock, personal alert systems can inform individuals who are DHH about various sounds around the home such as those created by a telephone, doorbell, smoke alarm, or an alarm clock by being wirelessly connected to each item. When one of these devices is activated, it sends a signal to the personal alert system, which may provide a visible or vibrating warning, such as on a wristwatch, or phone (Kim and Kim 2014; NDCS 2017).

In addition, current mobile devices may capture vibration signals nearby or a spoken public announcement that are poorly accessible to people who are DHH. Vibratory signals through mobile devices have proved to be effective when their duration is long, around 13–14 s (Harkins and Bakke 2011). Of course, it is important to stress that current streaming technology is able to link several devices, including mobile or non-mobile ones, to the user's personal hearing devices (hearing aids and cochlear implants) (NDCS 2017). That is, the alert signals, which are usually auditory ones, cannot only be sent to the mobile device as vibrating signals, but they also can be directly streamed to the hearing aids or cochlear implants and be perceived as auditory signals by users with functional hearing.

Conclusion

Assistive technology can play a major role in the access and participation of individuals who are DHH in daily life, in a variety of environments, such as home, work, school, playgrounds, sport activities, social events, and cultural centers. There is a wide range of assistive technologies that can benefit different users depending on their functional hearing, the way that they communicate, and the environment where they are. Nevertheless, despite the positive role of assistive

technology, many individuals who are DHH do not use them.

The use of assistive technology has been limited due to psychosocial factors such as social stigma, low self-esteem, and cosmetic appearance associated with the use of these technologies, as well as to difficulty in adjusting to using a new technology (Cienkowski and Pimentel 2001; Rekkedal 2011). Such concerns seem to have been addressed lately by the mobile phone technology, which allow users to control their hearing aid or the cochlear implant through their mobile phone. In this way, users do not need to carry extra devices, and they also avoid the social stigma that concerns some of them because the use of a mobile phone is common (Compton-Conley n.d.). Another reason for the low use of assistive technologies is that in many countries these devices are not available or are costly. Also, the regulations regarding accessibility and the implementation of these regulations vary from country to country. Although personal amplification systems, such as hearing aids or cochlear implants, seem to be widely used, assistive technologies are not always so widely known or provided.

Therefore, in order for these technologies to become more widely used, they need to be broadly available, and additionally there is a need for the mandatory application of Universal Design principles that would address the needs of clients with different characteristics and skills including individuals who are DHH (Office of Educational Technology 2010; Varzhel et al. 2017). Under Universal Design, assistive technologies will be included in the planning of buildings, events, learning programs, and all products ensuring or facilitating the access of individuals who are DHH.

Assisting People with Autism Spectrum Disorder Through Technology

Nigel Newbutt

University of the West of England, Bristol, UK

Introduction

This entry seeks to provide a review and overview of technology that has been used to support autistic people. The aim of this entry is to provide an overview of technology used by autistic groups contextually and historically. Materials covered will include virtual reality technologies, touch screens, and more traditional media types (i.e., multimedia). The entry will include a historical overview of the field and provide some detailed explanations of technologies that have been used, mainly in scientific literature. In addition to this, the entry will explore autism and paradigms of exploring the field of technology used by autistic people. Finally, the entry concludes with some views, perspectives, and the potential for future work in this area, coupled with messages for practitioners and ways that technology can be most fruitfully used with, by, and for autistic groups.

Autism and Autism-Based Paradigms

Autism spectrum conditions (ASCs) are pervasive and enduring conditions, characterized by a qualitative impairment in social functioning and communication and restricted or stereotyped behaviors. Autism is also described as a neurodevelopmental condition characterized by core differences in social communication, interaction, and repetitive behaviors across a variety of contexts. In terms of autism being described as a “spectrum,” there are ways that this has been contextualized in recent years. Most recently, a “spectrum” is referred to as people who meet the main criteria (outlined above) in addition to having associated learning difficulties – or not. So terms such as “high functioning” and “low

functioning” are used and associated with autistic people without or with learning difficulties (respectively). This entry takes the position that using terms such as “autistic people” is preferred by the autistic community and as such will use this language.

In terms of its impact, the National Autistic Society predict that “Around 700,000 people in the UK are on the autism spectrum [...] together with their families, this means autism is a part of daily life for 2.8 million people” (National Autistic Society 2018). This number of autistic people reflects about 1:68 within the UK and, in studies undertaken in parts of the USA, can rise to 1:56. In addition, the condition is reported more in males than females with about four in every five autistic people being male. Recent evidence tends to suggest that one reason for this male/female ratio could be due to females being better able to shield their condition. Notwithstanding various limitations, discussions, perspectives, and reasons related to the data above (and either way), there is a growing population of autistic children and adults. As diagnosis, support, and educational provision are improving, there is an increasing need to identify ways to support key areas related to education, support, and transition from adolescence to adulthood.

Despite increasing diagnoses and better recognition and support for autistic communities there are still limited positive outcomes for autistic youths and adults. There remains a significant gap, for example, in employment prospects for autistic adults. With data from the UK, for example, reporting about 32% of autistic people in paid employment (this falls to 16% for data related to full-time employment), there is a specific and urgent need to consider ways to help improve this. A number of approaches that have been identified in recent years include (1) identifying and positively utilizing the strengths of autistic groups, (2) educating employers and others as to how autistic individuals can successfully be integrated into workplace settings, and (3) employing a range of technology tools to help assist successful transition routes into employment. These factors can also be said to apply to a range of other contexts including education,

socializing, learning, and training, to name a few. The specific focus of this entry is to present ways in which autistic people are engaging with and using a range of technology tools to help assist in a variety of ways. The following sections will outline:

1. Paradigms and perspectives of evaluating and using technology for autistic groups
2. Why technology has been seen to be a good fit for autistic users
3. Types of technology use for autistic users
4. Conclusions and future directions

Paradigms and Perspectives

It is important to understand that technology applied to autistic contexts has been situated in a range of perspectives or for the purposes of research: paradigms. This is useful to briefly mention as it *can* cause tensions between not only the types of data that are used to report studies across paradigms but as it can also raise concerns for terminologies and the applied use of technology. In medical-based perspectives, autism has been seen as a disorder and in many cases reported as requiring “interventions” to help improve the skills and therefore outcomes of autistic people. Technology-based research within this paradigm has sought to develop interventions with a view that autistic individuals can have gaps/problems in their condition managed. These examples have highlighted a deficit-based model of autism.

However, and in recent years, there are other paradigms and perspectives that have sought to develop the use of technology as a way to support, develop, and enable autistic people. These types of studies and projects are situated more closely, in many cases, toward a socially integrated, progressive, and accepting views of autistic people. This is not to suggest that medical-based ideals have not been accepting or socially progressive, but rather that they tend to focus on fixing deficits in individuals. Constructivist and interpretivist models accept differences and try to situate their work within understanding how autistic people view the world and how others view them. In

fact, most recently (2018) there have been initiatives toward recognizing autistic individuals’ strengths and how these can be harnessed and utilized within a range of opportunities. The role of technology in constructivist domains tends to seek ways of augmenting and adapting the lives of autistic people. For more on this perspective and overview, please refer to the work of Milton (2014).

Next, various types of technology used with/by/for autistic groups will be introduced, outlined, and discussed.

Why Technology and Autism?

Before discussing types of technology used by, with, and for autistic groups, the following table provides an overview of the technology discussed in this entry along with definitions related to these technologies (Table 1).

Key features of virtual environments have been cited as having potential benefits for autistic individuals as they can be individualized, controllable and predictable and offer “safe spaces” for users to learn new skills (Parsons and Mitchell 2002; Kandalafi et al. 2013). This means that autistic individuals can practice interactions within a realistic environment that can be programmed to reduce sensory and social inputs to a manageable level.

The publication of several conceptual and state-of-the-art reviews in recent years has focused the debate more widely on issues relating to the use of VR by, and with, autistic individuals (see Bellani et al. 2011; Parsons and Cobb 2011; Parsons 2016; Bradley and Newbutt 2018). In addition, the immersive nature of virtual environments (VEs) has been shown to enable a sense of presence for autistic adolescents (Wallace et al. 2010) as well as providing a motivating tool for learning (Parsons and Mitchell 2002). There is evidence that the ability to individualize, rehearse, and repeat social scenarios across different contexts has afforded opportunities for the generalization of social skills learned in VE to everyday life interactions (Didehbani et al. 2016; Parsons and Cobb 2011; Tzanavari et al. 2015).

Assisting People with Autism Spectrum Disorder Through Technology, Table 1 Key terms, abbreviations, and definitions used in this entry

Term in full	Abbreviation (if applicable)	Definition with reference point
Virtual reality technology	VRT	This is used as an umbrella term to describe the technologies below and in general, encompassing all virtual reality-type experiences
Virtual reality	VR	Virtual reality specifically refers to the computer-generated simulation of a three-dimensional image or environment that can be interacted with in a seemingly real or physical way by a person using special electronic equipment, such as a helmet with a screen inside or gloves fitted with sensors (ref: Google.com)
Virtual environment	VE	A computer-generated, three-dimensional representation of a setting in which the user of the technology perceives themselves to be and within which interaction takes place (ref: Dictionary.com)
Collaborative virtual environment	CVE	The same as a VE, plus the ability to collaborate with others within a 3D simulated space
Single virtual environment	SVE	The same as a VE without the ability to interact with others
Virtual world	VW	A virtual world is a computer-based online community environment that is designed and shared by individuals so that they can interact in a custom-built, simulated world. Users interact with each other in this simulated world using text-based, two-dimensional, or three-dimensional graphical models called avatars (ref: Techopedia.com)
Head-mounted display	HMD	A type of computer display device or monitor that is worn on the head or is built in as part of a helmet. This type of display is meant for a total immersion of the user in whatever experience the display is meant for, as it ensures that no matter where the user's head may turn, the display is positioned right in front of the user's eyes (ref: Techopedia.com)

Note: Link to full-res images that are included, is below. <https://www.dropbox.com/sh/20252dtc1a14kmp/AAA0D80gWafQmkYdwsf2Ooy0a?dl=0>

The recreation of realistic settings and contexts by researchers and developers has enabled skills to be learned and reinforced in VE in ways which were not always possible or, more problematic, in real life. A range of different scenarios have been designed to enable autistic individuals to learn skills that may be supportive of independent living, positive social interactions, or maintaining their personal safety. For example, researchers have developed VE that recreate celebrating with a friend and meeting strangers (Kandalft et al. 2013) or crossing a road safely (Strickland et al. 1996) and learning social conventions (Parsons et al. 2006).

This research indicates that VRTs have valuable potential for both support and the education of children, young people, and adults who are autistic. Many studies show promising results regarding users learning and generalizing new

skills and knowledge and showing changes or developments in their responses over time (Parsons 2016). However, there remain significant challenges for testing the relevance and applicability of VR for autistic children in educational contexts.

Within the field of assistive technology (AT), various virtual technologies have been used with the aim to help and assist autistic people in a variety of ways. They have been used in ways to help enable spatial awareness (Strickland et al. 1996), to help understand facial expressions (Fabri and Moore 2005), to understand social skills and social awareness (Parsons et al. 2005; Parsons 2007), and as a tool to help support social cognition training (Kandalft et al. 2013). Additionally, Alcorn et al. (2011) have undertaken work in virtual environments to help facilitate joint attention cues. Studies within the area of

virtual reality technology (VRT) have mostly reported positive outcomes and highlighted how, in many cases, people with autism have adapted to VE interfaces (Parsons 2007; Guldberg et al. 2010), used VR with comfort and enjoyment (Strickland et al. 1996), developed social skills (Parsons et al. 2005), and found comfort in the communication afforded by VE interfaces (Fabri et al. 2004). In addition to this developing evidence-based, screen-based media is also something that research has concluded autistic people can be attracted to, in some cases more so than their typically developing peers (Mazurek and Wenstrup 2013). This highlights perhaps a preference for the use of material presented through screen-based media formats. For example, and as Mazurek and Wenstrup (2013, p. 1265) report: “Children with ASD spend approximately 62% more time watching television and playing video games than engaged in non-screen activities (including reading, studying, spending time with friends, and engaging in physical activities).” This is also a view previously reported by Mineo et al. (2009).

Examples of Technologies Used to Support Autistic Groups

This section seeks to identify and outline a range of technology tools that have been used by, with, and for autistic groups. Before moving onto this, the following figure (Fig. 1) provides an overview of the timeline for technology used with autistic groups. This is situated within the evidence-based research conducted over a period of time (1970s–2018). This is not meant to represent a detailed overview, but rather some key points when specific technologies have been used, applied, and evaluated with autistic individuals and groups.

While Fig. 1 provides a visual representation of key technologies across the last 40 or so years, the following sections aim to provide a more detailed overview and review of these technologies and where/how they have been applied for autistic users.

Virtual Environments and Collaborative Virtual Environments

Initially within the area of virtual reality technologies (VRTs), Strickland et al. (1996) presented an early study that assessed the effectiveness of virtual reality (VR) as a learning tool to engage autistic children; their study was primarily designed to determine if autistic children would tolerate VR equipment and respond to a computer-generated world. They considered the differences between VR and computer programs, the level of interaction with computer-generated images, and independence in determining motion and objects in a VR world as a way to present real-life experiences. The use of VR for autistic children was considered, based on sensory problems, lack of generalization, visual thought patterns, individualized treatment, and responsiveness to computer technology. The aim of the study was to help children with autism learn how to cross a road safely. They used VR helmets to immerse the users in a 3D environment, so that users could identify cars, the colors of objects, and how they were moving. The children were presented with various scenarios to determine generalization and were asked to “walk” into the scene and interact with signs. Conclusions gained from the study suggested that the two participants were able to interact with the environments successfully (accepted the virtual helmet, tracked in-world objects, moved their bodies and heads, located in-world objects, and moved toward them). In addition the study suggested that the participants appeared to become immersed (labeling in-world objects and moving their bodies interactively). These aspects tended to suggest that VR afforded far-reaching advantages to autistic children, including encouraging interaction, exploring, and learning. A limitation of the study was the small number of participants included; while two children accepted the use of VR devices (helmet, joystick, gloves, etc.), it does not follow that others would. Newbutt et al. (2016) readdressed these points later (in 2016). This will be discussed in later sections of this entry.

Assisting People with Autism Spectrum Disorder Through Technology, Fig. 1 Overview aligning key technologies used with autistic groups since the 1970s to 2018

Building on the work of Strickland et al. (1996), Charitos et al. (2000) designed a virtual environment that was controlled by virtual reality input devices, to aid the organizational skills of people with autism. The study aimed to teach social skills through providing a virtual interface for people with autism to navigate through. Charitos et al. provided a series of reasons why computer-based systems are well suited for autistic people, based on the work of Murray (1997). Examples cited by Murray included being able to set clear boundaries and controlling the stimuli (through a step-by-step process). These both allowed for greater control and focus of material in the presentation and learning. Another advantage cited by Murray links to joint attention and restrictive context. These both, in some ways, play to the strengths of autistic people in that focus of interest can be taken into account in addition to restricting other sources of information. Overarching these aspects, Murray suggests that safety, flexibility, and adaptability can all be instilled along with a sense of prediction.

On this basis, Charitos et al. (2000) proposed designing a virtual environment to aid children with autism in undertaking everyday tasks. This, more specifically, pertained to “returning home” and builds on a traditional teaching practice used within the school. It was an aim of the project reported in this paper to “improve the potential for effective teaching” (Charitos et al. 2000, p. 150).

Interestingly, although not surprisingly, Charitos et al. arrived at similar conclusions to those of Strickland et al., including the notion that structured environments go some way to help users feel confident and that a range of input devices could be used. The work presented by Charitos et al., while including more participants than that of Strickland et al., still has limited participant detail which would help provide useful contextual data, helping us to better understand the study in the exploratory manner it is intended.

Elsewhere, Fabri and Moore (2004) developed a simple platform that integrates the use of images (avatar representations) and animated facial expression sequences, to help in the understanding of facial emotion and communication for users with autism. They present three stages to their

product: (1) avatar representations in isolation, to help initial emotional understanding; (2) prediction of emotions in contextual situations – own feelings and feelings of others; and (3) avatar emotional representation, paired with a selection of events. The tasks involved recognition of an emotion from a facial expression, selection of an expression to represent an emotion, and prediction of an expression. The user at stage 3 is required to select an event that may have caused an emotional response and is asked to infer their own emotion to that of another (cause and effect). In order to identify whether participants were successful in selecting appropriate emotional avatars for each section of their program, Moore et al. compared the observed responses of the participants to the questions against chance responding. The results showed that over 88% of participants performed above the level of chance. Moore et al. conclude that the study offers evidence that the majority of participants involved were able to interpret and understand the emotions of the avatars appropriately. This study demonstrates that people with autism have both the ability and predisposition to use CVEs and that they can, via this medium, identify emotion, apply emotion, and predict emotion from facial expressions (Moore et al. 2005).

This study does, however, offer clear evidence that using virtual animated facial expression can help autistic users to understand and decipher emotion. The study recognizes that a small minority of participants found it difficult to understand the emotions represented by the avatars, and for this reason, more details on the individual participants would have been useful, allowing greater insight into who CVEs could be most beneficial for.

Cheng and Fan (2008) also used a CVE to experiment with the representation of emotions for autistic children. This study included 2D image representations of 3D avatars, rather than 3D avatars as used in Parsons et al. (2005). In Cheng and Fan’s study, ten participants ranging from 5 to 17 years old were selected; they all had a local (school) diagnosis of autism. The study was focused on considering the role of expressive avatars used in conjunction with text chat communication or computer-mediated

communication (CMC). To investigate this aspect of CMC, the authors conducted an interview with the ten participants via the CMC program created for the purpose of the study. One of the primary aims was to judge how the participants with autism responded with text and expressive avatars throughout the communication process. In other words, they provided an interface that allowed users to talk one-to-one, through the medium of text and visual representations of faces. Each of these faces displayed a different emotion. They were modeled in 3D, then rendered and exported as 2D images. Cheng and Fan concluded that eight of the ten of participants were able to successfully use the system to identify emotion as represented by a graphic. Moreover, the participants were able to interpret the emotions of others through the system.

Another study that builds on the work carried out by Strickland et al. (1996) and Cromby et al. (1996), and adds to limited knowledge in the field, is that of Parsons et al. (2006), where newer and different technology is applied. The study of Parsons et al. (2006) involved the creation of a virtual environment (VE) for the purpose of improving social skills in two autistic children. This study included two children within the high-functioning range (i.e., without ID). However, Parsons et al. introduce a VE that involves navigating through simple scenes (a café and a bus stop), rather than presenting a one-to-one communication tool (building on the findings of Cobb et al. 2002). In other words, the users were able to navigate through an environment or space as part of the simulation. The scene includes other characters, who are passive, but are pre-programmed to respond to user input. In their analysis, Parsons et al. consider five areas for review and discussion: (1) repetition of response, (2) physical and literal interpretations, (3) treating the VE like a game, (4) putting learning into practice, and (5) recognizing changes and usefulness. Repetition of response was an area of the research that provided mixed results. Both users would navigate through the café scene in exactly the same way, individually, each time they approached the tasks, although one of the

participants would maintain their route through the scene despite encounters with chairs, tables, and other objects.

Parsons et al. (2006) also report some repetitive statements/verbal responses, although the participants did change some responses in the VE, in particular choices of food ordered and when asking if they could sit down to eat their food. Furthermore, the participants sat in different places each time they used the environment, suggesting that they were “responding differently to the changing demands of the VE” (Parsons et al. 2006, p. 13). Literal interpretations were an issue for the participants: one of them could not understand why, for example, they could not sit in an empty chair when the person sitting at the table said, “Excuse me, that seat is taken.” The participant thus highlighted a problem with accepting that a seat can belong to a person socially. However, after repeating this several times, and with some help from the facilitators, the participant was able to understand the need to ask if a seat is taken, out of courtesy.

One of the main difficulties in using VEs, and in particular for autistic users, is in creating the perception of reality, so that the user can identify and provide natural responses. It was noted by Parsons et al. that the participants viewed the VE as a game and would not therefore interact as they might in real life. However, it was observed that there were occasions when the participants would apply real-world and appropriate actions to the VE. A specific example relates to the choice of seats on a bus – the participant chose a seat that had enough legroom and one that was facing in the preferred direction. This perhaps shows how immersed the participant had become and that they did view the VE as a “real world.” A similar finding, but with more participants, was reported in an earlier study by Parsons et al. (2005).

In sum and taken as a whole, the role and potential of VRTs and specifically VEs, for autistic users, has been shown to have some benefits and possible useful application for skills development, specifically testing social situations and visiting places. Both of these contexts can

be designed in ways to reduce cognitive pressures and real-life consequences or indeed any other types of interactions. This, along with the predictable nature of using a computer simulation, can provide a suitable or preferred space for autistic groups. The next section will briefly discuss virtual worlds and how these have been used by and for autistic users.

Virtual Worlds

Boulos et al. (2007) considered the use of Second Life (a type of virtual world) in medical and health education. Their article helps to provide a clear indication of the potential of VWs in health-related conditions – in an educational context. The authors discuss and present two case studies of recent and successful VW endeavors, in Second Life (Healthinfo Island and VNEC – Virtual Neurological Education Centre), and are able to present a detailed insight into the advantages afforded by the platform. These include the use across a distance-learning education model and for older people and people with physical disabilities; real-time social networking and state-of-the-art graphical representations are also highlighted. Boulos et al., in addition, identify several challenges pertaining to the use of VWs. These include Internet addiction, gambling, violence, trust, identity, copyright, and vandalism. These all relate to ethical concerns and are something all VW studies need to address and consider for their user groups, more broadly.

Recently, Stendal and Balandin (2015) report on the use of Second Life and therefore VWs. Here they suggest that “people with ASD enjoy using a virtual world and may feel more comfortable communicating in the virtual world context than the physical world” (p. 1591). They also highlight several self-reported affordances of VWs including:

- Autistic people enjoy using a virtual world and can feel more comfortable communicating in the virtual world context than the physical world.

- Virtual worlds offer a venue for autistic people to be a part of a virtual society.
- Virtual worlds offer an arena for autistic people to meet their peers on equal terms, not being dependent on social cues, which in the physical world can be a barrier for this group (Stendal and Balandin 2015).

These are similar to findings reported by Newbutt (2013) who also found that autistic children reported preferences for using text chat to communicate with others (their peers and teachers), in a virtual world. The fact that text chat can be undertaken at the pace of the individual, and that extra thought can go into what they would like to say, helps, especially autistic individuals, in communicating with more confidence.

Virtual worlds (VWs) also offer potential for autistic users, and in fact one of the largest, Second Life, has many registered users who have such conditions (Salman 2006). However, to date few, if any, formal studies have been carried out to assess the impact such environments are having on users with autism, even though virtual worlds have contributed to this field of study and could provide a form of assistive technology.

In a brief correspondence, Fusar-Poli et al. (2008, p. 980) hypothesize that Second Life could be used to “develop social and communicative skills of autistic people.” They go on to outline the same affordances as Cobb, Parsons, Moore, and Fabri, stating that “. . . it allows anonymous social interactions, and provides high levels of social interactivity but without complex linguistic and social-behavioral processing necessary for face-to-face conversations” (Fusar-Poli et al. 2008, p. 980). Further, Fusar-Poli et al. suggest that it “levels the playing field for autistic people,” in that it offers a new space to rehearse social skills. This last statement, although a value statement, does suggest that people with autism and related conditions can enter VWs without any preconceptions or assumptions placed upon them. Fusar-Poli et al. also say that a secure and safe space is needed in which social mistakes can be made so that a sense of collaboration and

community can be established. The authors propose Second Life as an ideal tool for allowing participants with autism to benefit from the affordances mentioned.

In a specific example of the use, potential, and application of VWs, a charity (Autus; <https://www.autus.org.uk>) has implemented the use of a VW to help connect and open employment opportunities for autistic groups in the UK. Here they have designed virtual job centers (in a virtual world) to help provide access for autistic groups who might find it difficult to access resources in real-world job centers. There are other such initiatives designed and implemented by the group, all building on the affordances of VWs for autistic groups. Figure 2 provides an example of how this looked, visually.

It is through the affordance of VWs that can provide a fruitful space for autistic users to develop confidence and test situations out. The use of text chat and body movements (and facial expressions) can all be used as/when to help open modes of communication in VWs. This has been seen to be a positive effect in the work of Autus (above) and the work of Newbutt (2013).

More recent developments have provided newer lines of inquiry (i.e., touch screen devices)

and renewed lines of inquiry (i.e., VR and HMDs). The next two sections review work in the area of both touch screen devices and HMDs.

Touch Screen Devices

The arena of touch screen devices applied to autistic groups is something first investigated since the introduction of affordable and freely available touch screen technologies, namely, the iPad. Since then many studies have sought to investigate the possibility of how iPads (and other touch screen devices) can be used to develop communication, social, and initiation skills. For example, and recently, Xin and Leonard (2015) investigated the role of an iPad in developing communication skills in “three 10 years old learners diagnosed with autism who present little or no functional speech” (p. 4154). As a result of using an iPad, the authors concluded that all students increased initiating requests, responding to questions and making social comments in both class and recess settings. This provides some positive and helpful insights to the way that iPads and touch screen technology can be used to help aid communication endeavors of autistic users.

Assisting People with Autism Spectrum Disorder Through Technology, Fig. 2 Example of interface developed by Autus for an employment project. Using a

VW to help provide access to employment services, removing the need to visit a real-world job center (in the UK)

However, and as with many of the studies already reviewed, the sample was very small and so generalizing across populations is impossible; therefore, the study is mainly contextualized within the details of the specific project.

In earlier work, Alzrayer et al. (2014) surveyed all previous (previous to 2014) studies conducted with autistic users related to touch screen devices. They found that “tablet-based devices, especially iOS devices (i.e., iPad and iPod Touch) were highly effective in increasing the communication skills of individuals with autism” (p. 179). In addition to positive reported outcomes for communication, the authors found that touch screen devices “also have positive effects on decreasing challenging behaviors” (p. 189). This started to provide some insights that suggest touch screen devices not only have educational outcomes for autistic users but that they could also be used and implemented as a way to help calm users. However much more work is needed to validate both these suggestions.

In more recent work, Fletcher-Watson et al. (2016) undertook a randomized control trial of an iPad App to “evaluated a technology-based early intervention for social communication skills in pre-schoolers” (p. 771). The authors developed an app with the aim to develop specific outcomes for communication domains (reciprocation, social, words, etc.). Most interestingly, this study found that the “intervention did not have an observable impact on real-world social communication skills” and they suggested that “caution is recommended about the potential usefulness of iPad™ apps for amelioration of difficulties in interaction” (p. 781).

Therefore, it is evident that the possible potential of touch screen devices is mixed and evidence is contradictory. The work of Fletch-Watson and colleagues included a large sample, larger than work carried out previously. However, it should be underlined that this was only the case for the app that the authors used in their study – it does not mean all apps would yield the same results.

Despite the range of evidence associated with touch screen devices, there should remain positive attitudes toward their use for autistic groups. At a very fundamental level, touch screen devices

provide ways for nonverbal users to effectively communicate with caregivers and other people they need to communicate with.

Virtual Reality Head-Mounted Displays (VR-HMDs)

This technology has recently (2016–2018) become relevant and of interest – again – as it was first used in 1996 by Strickland and colleagues. They used the technology as a tool for teaching road safety and also to assess whether autistic children would be willing to wear a large HMD. However, the work of Strickland et al. (1996) was based in a lab and involved only two children, who were both encouraged to use the technology. As there have been a range of HMDs since the introduction of the Oculus Rift™ and increase in content (i.e., software) via the Steam network (<https://store.steampowered.com/>), there was a sudden and interesting need to investigate the potential of this technology for autistic groups. This was especially timely as there were many reports (without evidence or data) suggesting that VR and HMDs were a good fit for autistic users. However, with so few studies, it was difficult to assess the potential of HMDs without first asking autistic users about their willingness to wear and experience VR, especially based on concerns around sensitivity concerns (i.e., wearing a headset) and possible side/negative effects of HMDs (e.g., sickness, eyestrain).

As previously mentioned, the acceptance of VR technology among users with ASD has been studied over the last decade. Although some studies have established a safe way/process for the use of VR technology among autism populations, the technology itself has evolved and advanced in many ways since earlier work of Strickland and colleagues. For instance, VR technology and the head-mounted display used to be only an extension of the traditional monitors, which merely increase the viewing size and the viewable angle. The users of these VR devices acted as a passive role and did not have control over what was presented to them. Much has changed in the VR arena. The interaction

components have since been introduced and integrated in the VR applications. For example, users can now use a joystick to browse and maneuver in the virtual space. In addition, more current head-mounted display can also capture and respond to users' head movement to simulate a real-world 3D experience.

In addressing the need for a timely examination of HMDs (the newer generation), Newbutt et al. (2016) asked questions in a study related to acceptance of HMDs for autistic groups (a range in terms of age and the spectrum; remembering this relates to associated learning difficulties – or not). The findings from this work provided insights of how an autistic group felt about wearing a HMD and experience a range of VR experiences and how they reported sense of presence, immersion, and negative effects. Results, using an Oculus Rift HMD, highlighted a general level of acceptance (100% willing to try the HMD on and experience two VR scenarios) and high levels of self-reported presence and immersion. Most vitally, negative effects (i.e., feeling sick, eye-strain, etc.) were reported as being very low. These results were reported across an age range of 17–53. The equipment used was portable and taken into a workplace setting. The equipment used can be seen in Fig. 3, while Fig. 4 shows more recent technology (HTC Vive) being used in a school (in 2018).

Currently (as of 2018), there is a plethora of head-mounted displays available for the general public to purchase and use in their daily life. Depending on the purpose and the affordable budget, one can select inexpensive VR goggle such as the Google Cardboard, which costs approximately 20 dollars a pair. The design of Google Cardboard is to insert a smartphone into a pair of goggles made of cardboard with two lenses to simulate the 3D immersive effect. Because of its low-cost design, there is no audio or interactive component built in for the device. Users merely use it to simulate a visual 3D effect. The more sophisticated options are also available such as Samsung Gear VR, HTC Vive, and Oculus Rift (ranging from \$400 to \$800 without associated gaming computer, currently about \$1300). These VR devices capture the user's

Assisting People with Autism Spectrum Disorder Through Technology, Fig. 3 Example of VR-HMD kit used in Newbutt et al. (2016) study, highlighting the size, portability, and unobstructive nature of HMDs in 2016. This equipment was tested in a center for autistic groups in the USA

Assisting People with Autism Spectrum Disorder Through Technology, Fig. 4 Example of an HTC Vive kit being used with an autistic individual in school, again highlighting the possible inclusion in school-based settings. This was trialed in UK schools

head movement and can be used to play video games.

Despite the potential of VR and HMDs, there are only six studies that comprehensively report of

the use and/or potential of HMDs for autistic groups. These are reviewed by Bradley and Newbutt (2018) and cover work reported in the following studies:

1. Adjorlu et al. (2017)
2. Bozgeyikli et al. (2017)
3. Cheng et al. (2015)
4. Mundy et al. (2016)
5. Newbutt et al. (2016)
6. Strickland et al. (1996)

The work covered in these studies includes acceptance, willingness to wear HMDs, and the potential for learning and transferring learning using HMDs, mostly reporting positive findings in this area. However, there are several gaps and opportunities that arise from reviewing this work.

Though several studies had an element of participatory research methodologies, only two explicitly sought feedback from practitioners about the intervention (see Adjorlu et al. 2017; Bozgeyikli et al. 2017). This type of information is valuable and would enable more robust recommendations to be made on the sustainability of educational interventions and approaches using -VR-HMD technologies within educational, health, or community settings. Furthermore, the inclusion of autistic individuals in the research was predominantly in the role of passive participants whose experiences of the interventions were primarily gained through quantitative data. It can be argued that the lack of qualitative data, i.e., interviews with participants, limits our understanding of how they perceive VR technology and the use of HMD. It is therefore important to evaluate both outcomes and the process of implementation of VR technology through the involvement and experience of autistic individuals and the practitioners who work with them.

The variance in both technologies used (including how realistic the VEs are, type of HMD, and how tasks were carried out) and the diagnostic features of the autistic participants supported the finding that “the state-of-the-art in the literature is that there is no single study, or series of studies, that has systematically unpicked and interrogated the ways in which these features

may combine to influence responding and understanding” (Parsons 2016, p. 153). As with other research in this field, there has been a focus on autistic children, young people, and adults who have average or above average IQs and at therefore autistic without intellectual difficulties, which means the findings of these studies may not be applicable to a wider range of autistic individuals. The heterogeneity of response to VR-HMD applications and experiences indicates a need for further research that should take account of both the characteristics of this population and the specific features, characteristics, and affordances of this technology, to consider how these features might best support and motivate them. The issue of veridicality is of importance in this context, and the results from the six studies were mixed. Promising results were reported by Newbutt et al. (2016), with participants showing high levels of engagement, spatial presence, and ecological validity within VEs. In contrast, participants gave a more nuanced response in the study by Bozgeyikli et al. (2017) and indicated that while they were immersed in the VR activity, they were aware it was not real. As such, more work is needed on how VR-HMD technologies can be designed and developed to act as an authentic real-world experience for this population.

Conclusion

The increase of multimedia computing within the area of educational support for children with autism has been the focus of much research, from the early works of Colby (1973) and Heimann et al. (1995) to the work of Silver and Oakes (2001). These published works examined specific skills that multimedia could address in the educational development of children with autism. Through such studies, an argument has been constructed, for the use of virtual environments in providing a unique affordance for users with ASCs. Scholars such as Strickland et al. (1996), Parsons et al. (2005, 2006), Wallace et al. (2010), and Cheng et al. (2010) have each explored the role of immersion, realism, engagement, and

learning within virtual environments. Building on this, Kandalafi et al. (2013) have provided a specific example of the role virtual worlds can play in social cognition training. Yet, there remains a limited understanding in the literature of users' perspectives with a range of technologies.

Overall, the area of technology used by autistic people, and the potential benefits they hold, is still at an early stage in terms of research. While this field was developed and initiated in the 1970s, there has been slow progress with limited evidence related to:

- What types of technology are most suitable for autistic people?
- How and when should technology be used?
- For what age groups and levels of associated learning difficulties should specific and particular technology be used?
- Where is technology best deployed and utilized for autistic groups?

So far these questions remain underexplored in research studies, and so evidence supporting these is difficult to locate. Moreover, if technology is to have real potential for autistic groups, there is an urgent need to address the what, why, where, and how questions if there is to be more upscaling and utilization of technology for autistic people. Addressing these questions will also help to enable key stakeholders to place technology in the hand of the people it can most benefit. At the moment this is not happening.

In addition, and as highlighted above, no studies have applied a longitudinal or mixed-methods approach to this area, something that would yield a far better picture in terms of the longer-term outcomes, frameworks for continued application of technology (updates, development, versions), and refined software/hardware that might be most suitable and applicable in a variety of contexts (school, home, centers, etc.).

The future for technology used by, with, and for autistic people remains positive, especially based on nearly 40 years of evidence using a range of technologies. By working more closely with autistic advocates, groups, and individuals,

the field will be better placed to design, develop, and deploy technology that is suitable, usable, and effective in the future.

Assisting People with Physical Disabilities Through Technology

Katerina Mavrou

Department of Education Sciences, European University Cyprus, Nicosia, Cyprus

Synonyms

Accessibility; Assistive technology; Augmentative and alternative communication; Physical access

Introduction

The term physical disabilities often refers to a broad range of disabilities of people facing difficulties in limitation on physical functioning, mobility, dexterity, or stamina. These may include orthopedic and neuromuscular disabilities (such as cerebral palsy, spina bifida, muscular dystrophy, rheumatoid arthritis, spinal cord injuries,

traumatic brain injury, multiple sclerosis, ALS, and other orthopedic difficulties inherent or acquired), as well as sensory disabilities (e.g., visual or hearing impairment), and chronic health issues, cardiovascular or respiratory difficulties. Furthermore, the complexity of a number of diagnoses of physical disabilities often involve identification of difficulties in various aspects and interrelated sectors of the human activity and quality of life. Hence, as Heward (2011) identifies, people with physical disabilities compose an extremely complex and heterogeneous population which is impossible to describe in a single set of characteristics and terms. Similarly the use of technology for addressing the needs of people with physical disabilities lies in a huge spectrum covering all aspects of everyday life such as sitting and positioning, mobility, transportation, physical accessibility, access to digital technology, communication, and learning and cognition, as well as medical devices for care and health conditions (e.g., assistive products for respiration, for dialysis therapies, etc.). For example, the ISO 2016 assistive technology classification holds an enormous list of assistive technology items that can be used for the needs of people with physical disabilities in all areas of life, including health, care and well-being, workplace, education, everyday life activities, and more (ISO 9999:2016 Assistive products for persons with disability – Classification and terminology, available at <https://www.iso.org/standard/60547.html> (accessed 20 February 2018)).

In order to maintain focus, as well as coherence with the structure and content of this volume, this present entry will mostly concentrate on particular aspects of the use of technology for people with physical disabilities (not including sensory disabilities as these are covered elsewhere in the volume), involving physical access to digital technology and connections to communication and learning. Specifically, the aim of this entry is to present examples of assistive technology products for the various needs of people with physical disabilities but also to identify and discuss methodologies and models of assistive technology assessment, issues of implementation, and barriers and opportunities. Previous research studies

through the years (e.g., Judge 2000; Copley and Ziviani 2004; Mavrou 2011a; Layton 2012; Mavrou et al. 2017) suggest that as the number of people using assistive technology increases, the following areas are highlighted as particularly significant: accessing assistive technology, matching needs of person to technology, funding for assistive devices and service provision, and training of professionals and family members. In the present entry, this discussion is further supported by an example of a research case study.

Technologies for Physical Disabilities: Examples for Access, Communication, and Learning

Historically the various definitions of assistive technology placed assistive devices in the framework of functionality and accessibility often leading to connections with physical disabilities and mostly physical access and mobility. Gradually these definitions developed through the social and human rights approaches to disability, indicating the role of assistive technology in reducing environmental barriers (Scherer 2005) and in promoting equality, quality of life, and participation (see definitions of the WHO 2017 and ISO 2016). Nevertheless, as mentioned earlier, assistive technology for physical disabilities is primarily connected to physical access and includes a range of low-tech or simple devices (e.g., walkers or pencil grips) to high-tech ones (e.g., power wheelchairs or digital communication systems) (Huang et al. 2009). In 2014 the World Health Organization launched the Global Cooperation on Assistive Technology (GATE) initiative which aims to actions that will promote access to “high-quality, affordable assistive products to lead a healthy, productive, and dignified life” for every person in need of assistive technology, targeting especially the low-resourced areas of the world (Global Cooperation on Assistive Technology (GATE) of the WHO, available at http://www.who.int/phi/implementation/assistive_technology/phi_gate/en/ (accessed 20 February 2018)). Among other activities in the framework of this initiative, a Priority Assistive Products List

(APL) was developed (WHO 2016), after a scoping review and a high range Delphi exercise. The list, which of course is not restricted, includes 50 priority assistive products and aims to provide the UN member states with a model from which to develop a national priority assistive products list according to national need and available resources. The majority of the products included in the list concern physical access and are very relevant to the needs of people with physical disabilities but at the same time beneficial for other groups of people facing different challenges. Nevertheless, the composition of the list indicates the significance of low- and high-tech assistive products for physical access and their relevance to the range of people that these are essential for.

Hence, in this section of the entry, an overview of the main assistive technology products is presented, identified as essential for physical disabilities (and not only) in the digital era. This overview includes discussion of digital technology access devices and augmentative and alternative communication for physical disabilities.

Access to Digital Technology

The growth of computer and digital technology led to the emergence of the field of human-computer interaction (HCI) and the researchers’ and developers’ considerations on the communication and interaction between humans (people as users) and the artifact (computers and technology). Researchers in the field of HCI study the ways in which humans interact with technology and how technology is designed to facilitate a meaningful and innovative interaction addressing the needs of each individual. Hence, the components of this interaction and the impact on the design of technology interface and the assessment of individual user needs have become a major part in assistive technology (Zaphiris and Siang Ang 2009). In simple computer science terms, the exchange/interaction between people and computers entails three basic aspects – input, process, and output – commonly translated into hardware and software applications. Nevertheless, Cook et al. (2008) argue that “the human/technology interface is more than hardware and inputs into the device.” Rather it entails other elements, which especially

in terms of physical access, include not only hardware for input but also elements of interaction in processing and exchanging information. As Veigl et al. (2017) suggest, nonstandard human computer interfaces are required for people with complex physical and severe motor disabilities, especially when these are a combination of difficulties that challenge the selection of a single access assistive technology tool. Hence, according to the (Cook et al. 2008) model (i.e., HAAT presented later in this entry), in assistive technology for physical access elements of control interface, selection set and selection method are considered, which are examined together with the desirable output (and outcome) as well as the advances of technology.

Control interface refers to the hardware used to operate or control a device, which for people with physical disabilities often includes alternative input devices. Examples of alternative input devices are *pointing* devices, such as ergonomic mice, trackballs, joysticks, head controls, or even keyboard keys and eye-gaze technology with mouse emulation software; *keyboards*, such as one-handed keyboards, large keys keyboards, customized overlay, and programmable keyboards; *touch screens and touch surfaces*, such as external touch screens, touchpads, and touch-operated mobile devices; *switches*, which are selection and input command devices that may be operated with different body parts and control movements; *voice recognition technology*, by which the user can control the device with voice commands; *eye-control technology*, with or without mouse emulation; and even *brain control (EEG)*, which seems to create new possibilities for HCI and mostly for people with physical disabilities.

Upon decision on control interfaces, in choosing assistive technology for people with physical disabilities, selection sets and selection methods need to be considered. According to Lee and Thomas (1990) and Cook et al. (2008), selection set is the items available from which choices are made, which can be presented in visual, auditory, or tactile modalities. In other words, selection sets may be letters (e.g., in the case of a keyboard as a control interface), braille (as tactile), auditory

scanning output (e.g., in the case of a switch as a control interface), and symbols (e.g., in the case of an augmentative and alternative communication system). As far as the selection method is concerned, this is defined as the basic method by which the user makes a selection that can be either direct or indirect. Direct selection (or direct access) is when the person identifies the target and goes directly to it by using voice, hand, finger, eye, or other body movement with appropriate control interface. Examples of direct selection for people with physical disabilities include the use of eye-control access systems, touch screens, pointing devices, voice recognition, etc. Indirect selection refers to selection methods where intermediate steps are involved (Cook et al. 2008). This is mostly relevant to the use of switches and scanning, where the possible targets are sequentially (in various modes) highlighted (by a visual or auditory signal or a combination) allowing the user to press a switch when the desired target is scanned. Scanning can be autonomous by the device, where speed, timing, mode, and other features can be customized or directed, where it is activated and controlled by the user through a control interface (same or other than the selection control interface) (Angelo 2000).

As the individual needs of each person with physical disabilities vary and are often complex, access devices (and control interfaces) require configuration in a number of aspects. For example, in pointing devices, adjustments include mouse control parameters such as click method, double click speed, dwell selection, pointer movement speed and sensitivity, pointer precision, size of target, pointer size, and target size (Lopresti et al. 2008). In addition, adjustment may involve other physical characteristics of the control interface such as size (e.g., of trackball) and the grip of the device (e.g., of a joystick) or issues of functionality in control and configuration through connected software (e.g., see Oppenheim 2016). Along the same lines with pointing devices, configurations are necessary for the effective use of any other control interface, and they concern size and space, activation and selection methods, effort, flexibility, and sensory and cognitive characteristics, as well as sitting, position, and

coordination of the person in relation to position and mounting of the devices. For some control interfaces such as the eye-gaze technology, configurations can be complex and may require long-term piloting, training, and adaptations (Borgestig et al. 2016).

In a great number of cases of persons with physical disabilities, assistive technology for access is significant in determining technology for supporting other aspects of life, mainly communication. Hence, technology concerning augmentative and alternative communication (AAC) for persons with physical disabilities and complex communication needs is discussed in the following section.

Augmentative and Alternative Communication for People with Physical Disabilities

Augmentative and alternative communication (AAC) refers to a variety of techniques and tools, including no-tech (e.g., pictures and paper-based boards, signs, and gestures), low-tech (e.g., communication switches), and high-tech (e.g., digital devices) to help individuals with limited, not functional, or absent verbal communication/speech (ASHA 2018).

There are a great number of AAC techniques and devices that are available to individuals with complex communication needs, and most of them can be applicable for people with physical disabilities. Nevertheless, in physical disabilities, access, as discussed in the previous section, is a major parameter in the design and development of AAC interventions, as well as for the selection of relevant technology. Often AAC systems are categorized as follows:

(a) *No-tech AAC systems*, which include gestures, facial expressions, body movements, formal gestural codes, or manual sign systems (such as official sign languages). For physical disabilities, such systems can be applicable in cases where individual's physical condition allows for signing, gestures, and movement of any body part. In severe physical disabilities, the use of eye gaze for pointing (looking) at what is desired or responding to yes/no

questions is very common and often effective for basic needs.

(b) *Low-tech AAC systems*, which are usually divided in nonelectronic and electronic systems. *Nonelectronic systems* include cost-effective techniques that are easy to make or obtain, and they may be *letter/words/phrases or graphic symbol displays* organized either in sets of *individual cards, boards, mats, or grids or communication books*. These may also include formal communication systems such as PECS (Picture Exchange Communication System) (Bondy and Frost 2001). In most of these systems, communication is achieved by gaining attention of the communication partner with disabilities, who expresses him/herself by giving (e.g., a card), pointing at or looking at a symbol/sentence/word. In cases of severe physical disabilities, choice can be performed by eye gaze through *visual displays such as eye-com/e-tran frame boards* which include limited number of items on transparent boards facilitating the observation of the user's eye movement toward selection by the communication partner. *Electronic systems* are devices that permit the storage and retrieval of messages, many of which allow the use of speech output, and they operate with batteries. They are also referred to as mid-tech AAC systems. These may be *communication switches of a single, dual, or sequential recorded messages, devices of multiple recorded messages, and talking albums (photo albums with recording function)*. These devices differ in size, shape, number of visual items (e.g., pictures or symbols or even objects), and recordings they can hold, as well as in fixed or changeable display. Fixed displays hold the same number of items and recordings, while in changeable displays overlays, and sometimes number of items/options and recordings, can change. Similar to nonelectronic systems, the use of electronic systems by people with physical disabilities depends on features of access. A great number of electronic systems are designed in a way that allows alternative access for physical disabilities, such as switches (with or without

scanning mode), clearly separated and large cells, buttons, or ports for external access devices.

- (c) *High-tech AAC systems* are also electronic devices, which are based on computer and digital technology. They can be either dedicated devices (i.e., used only for communication) or non-dedicated which are computer-based (e.g., laptop computer, iPad, tablets), which are adapted for communication use, and which are used for other functions as well. High-tech AAC systems permit the storage and retrieval of messages and allow the use of speech output. They are often called speech-generating devices (SGDs) or voice output communication aids (VOCAs). With the advances of mainstream technology and the evolvement of mobile technology, non-dedicated AAC devices are becoming more and more popular. For people with physical disabilities, the use of high-tech AAC is closely related to features of human technology interface and interaction (HCI) and more specifically control interfaces. In the past there has been a long debate between dedicated versus non-dedicated devices and their flexibility according to the needs of individual potential users, with non-dedicated devices gaining more attention. Nevertheless, nowadays dedicated AAC devices mostly run on a Windows[®] platform, and therefore they are becoming more flexible, than in previous years, in terms of adaptations for alternative access (e.g., eye gaze, switch, head control) for people with physical disabilities, as well as convenient for people with less complex physical disabilities due to embedded accessibility. On the other hand, new tablet-style mobile technologies hold other advantages such as availability as mainstream technology, cost, and weight, but they are in many cases challenging for people with physical disabilities in terms of physical access options for adaptations (Abbott and McBride 2014) and external accessibility. Nevertheless, the use of mainstream non-dedicated (tablet-based or other) devices for AAC largely depends on the availability and flexibility of apps or

software, respectively, for communication. For physical disabilities, it is important that such apps and software also allow for the use of alternative access such as switch or eye gaze; hence this is not only a hardware issue.

A great amount of literature provides evidence on the potential of AAC for people with complex communication skills (Smith 2015; Calculator 2009; Lilienfeld and Alant 2005; Clarke and Kirton 2003), including people with physical disabilities (for instance, cerebral palsy, traumatic brain injury, neurodegenerative disabilities). On other hand, Light and Macnaughton (2014) argue that “despite the strong evidence of the benefits of AAC intervention, the potential of AAC remains unrealized for many individuals with complex communication needs” (p. 99). Individuals with physical disabilities and complex communication needs are often included in the number of people that do not benefit to the expected extent from the potentials of AAC, due to various factors relevant to personal characteristics (Smith 2015), training and digital literacy (Mavrou et al. 2017), professional support and follow-up (Mavrou 2011a), opportunities for participation, user’s own evaluation of technology function, and others (Huang et al. 2009). Hence, in following paragraphs the main characteristics and elements for successful AAC use for people with physical disabilities are discussed.

Feature matching between technology and the human/user needs, context, and activities is vital for the success of AAC in physical disabilities (and not only). To this end, input, processing, output, and other properties of technology need to be taken into consideration. Input relates to HCI and more specifically to control interface. Consequently, the use of AAC devices by users with physical disabilities requires physical skill development, whichever the selection method may be (Cook et al. 2008; Kay 2014). For physical disabilities physical skill development should specifically take into consideration not only functionality and motor constraints (Costigan and Newell 2009) but also safety and performance of the user, in order to experience success in communication efforts for developing AAC users’

self-esteem (Smith 2015). One of the key elements is reduction of physical effort, and this is why one of the breakthrough technologies currently widely used of access and communication for people with severe physical disabilities is eye-gaze technology (Borgestig et al. 2016; Light and Macnaughton 2014).

Processing is related mostly with communication competence development, not exclusively relevant to physical disabilities, but to all possible users of AAC. It is not connected solely to physical skills but also to selection sets, vocabulary, and language organization and development. Hence, issues of message/vocabulary retrieval, symbol set selection, messages coding (e.g., color or number coding), and location on device overlay are important. In addition, successful communication competence development also relates to communication partners' role and programs for language development (Smith 2015). Nevertheless, for physical disabilities, an individual may be a good communicator but a poor technology interface controller or vice versa. In such cases, the challenge is to design AAC user training programs that will address the user's profile for both access and communication (Costigan and Newell 2009).

AAC system output is also one of the features that should match user's need, activities, and context. Output issues involve visual, auditory, and maybe tactile modes of the message to be communicated, as well as issues of compatibility and interfacing with other assistive technology (e.g., power wheelchairs). Hence, in physical disabilities, decision on the output feature of an AAC system lies upon the sensory needs and abilities of the person; the context, environment, and activities she/he is involved; as well as the possibility of using other assistive technology. The latter leads to the last feature discussed here, referring to other properties relevant to physical disabilities such as portability, positioning and mounting of the device, customization, as well as training, support, and follow-up.

Bearing in mind the aforementioned, assessment and skills development for physical disabilities play an important role in effective implementation of assistive technology for access and communication. In the following section, the

main assessment and support in assistive technology models and methodologies are discussed.

Methodologies in Assessment and Implementation of Assistive Technology for People with Physical Disabilities

Assistive technology assessment is a dynamic process which is conducted utilizing a variety of methodologies usually not specific to one area of AT, the outcomes of which consist the guidelines for AT implementation and plan for monitoring and measuring the effectiveness of this implementation. A number of AT assessment models are described in literature. The various models differ in certain ways, but at the same time they share the main characteristics of the fundamental assessment process (CSUN Center on Disabilities 2006). This includes identification of needs (after the person's referral), identification of desired outcomes, assessment of skills and the trial of technology, revisit of outcomes, and repetition of the process in case they are not met or acquisition and implementation of AT in case desired outcomes are met, together with a follow-up and follow-along plan. Though, no model is specific to physical disabilities, some of the most widespread AT assessment frameworks are presented here, which are largely oriented on tasks and activities linked to (among others) physical activity. Nevertheless, it is noted that AT assessment and disability assessment in general have been discussed and criticized under the various perspectives and models of disabilities (Edyburn 2001; Hersh 2010; Kay 2014). This discussion is out of the purposes of the present entry, but it is acknowledged here that application of any assessment and AT implementation process should respect the social and human rights models of disability.

Human Activity Assistive Technology (HAAT) Framework

This framework is proposed by (Cook et al. 2008) "for understanding the place of assistive technology in the lives of person with disabilities, guiding both clinical applications and research investigations" (p. 36). HAAT was developed to analyze

the complexities of a person with a disability, performing an activity within a context, especially when the use of assistive technology is part of that context, and thus it has four components: the human (including physical, cognitive, and emotional elements), the activity (including self-care, productivity in all aspects, and leisure – taking into consideration the ICF model), the assistive technology, and the context (physical, social, cultural, institutional) in which the first three are integrated (Cook et al. 2008). According to Hersh (2010), in HAAT model, context is at the top with a hierarchical structure of the components, as context is considered a determining factor in whether the person (human) successfully uses AT to carry out an activity within it. Angelo (2000) argues that HAAT is widely used for emphasizing the importance of access methods, and thus it is very relevant for physical disabilities in relation to AT assessment and the identification of appropriate control interfaces and other access elements.

Students, Environments, Tasks, and Tools (SETT) Framework

The SETT framework was introduced by Joy Zabala and “is based on the premise that in order to develop an appropriate system of Tools [...] teams must first develop a shared understanding of the student, the customary environments in which the student spends time, and the tasks that are required for the student to be able to do in order to be an active participant in the teaching/learning process” (Zabala 2005, p. 1) (Joy Zabala, Sharing the SETT Framework, available at <http://www.joyzabala.com/>). The framework sets a series of questions in each of the four areas (students, environments, tasks, and tools) in order to facilitate communication and decision making, in systematic way (Edyburn 2001), and it focuses on the need for collaboration and communication among the members of multidisciplinary assessment teams. The SETT framework is not specific to physical disabilities, but it is broadly used for determining assistive technology tools for the needs of children with physical disabilities as it provides a very clear structure for identifying functional and other needs of the student, as well

as determining the specific tasks (Watts et al. 2004). Specificity of task is very important for choosing and using assistive technology (tools) for physical disabilities, as identifying (interface) control devices and selection sets and methods can differ for each individual with similar characteristics and tasks, which may be slightly diversified.

Matching Person and Technology (MPT) Framework

Matching person and technology (MPT) is a framework introduced by Marcia Scherer (1998), which focuses on three primary areas: (a) determination of the environment factors influencing use; (b) identification of consumer personal and psychosocial characteristics, needs, and preferences; and (c) description of the functions and features of the most desirable and appropriate technology (for more details, see Scherer 2004, 2005). The assessment protocols suggested by MPT were developed by collaborative and participatory research approaches, and they take a personal, collaborative (user and provider working together) approach to assessing the potential technology need. Hence, components are assessed in terms of their positive or negative influence on the technology use (Scherer et al. 2005; Scherer and Craddock 2002), in order to avoid technology determinism, i.e., considering the perfect technology (artifact) while disregarding personal and environmental characteristics, resulting in misuse or even abandonment of technology (Seymour 2005). Though, similar to the above models, MPT is not specific to physical disabilities, there is an amount of research on its implementation and further development, which is based on work with people with physical disabilities (see Scherer and Cushman 2000, 2001) often with complex access and communication needs (Borgestig et al. 2016; Smith and Connolly 2008; Kintsch and DePaula 2002).

Comprehensive Assistive Technology (CAT) Model

Responding to the need for a more comprehensive approach to assistive technology assessment and consideration, the CAT model, introduced by Hersh and Johnson (2008a, b), gives a more

inclusive perspective by defining all components of the *person* (social, attitudes, and characteristics), *the context* (social and cultural, national, local settings), *the technology* (activity specification, design issues, system technology issues, and end-user issues), and the *activities* (mobility, communication, cognitive, daily living, education and employment, recreation). CAT is closer to the approach of the HAAT model, as it holds a similar hierarchical structure of the human assistive technology system with the four main components at the top level of person or human, context, assistive technology, and activity (Hersh 2010). Again not specific to physical disabilities, CAT provides assistive technology and disability professionals the opportunity to consider examination of physical access for individuals with physical disabilities, from additional angles than the ones discussed above. Hence, complex physical needs and access are examined from the prism of not only the activity setting but also the social and cultural context. In addition, CAT draws the users' and the professionals' attention toward the use of new (mainstream) technologies and their embedded accessibility characteristics. It also extends the connection of (assistive) technology assessment in education beyond the physical educational environment adaptations to the pedagogy of diversity and disability for inclusive education.

The development of various different models of AT assessment (not limited to the above) highlights the multifaceted nature of the use of assistive technology (Edyburn 2001), which is even more prevalent in the case of persons with physical disabilities and more specifically when complex communication needs are present. In a certain extent, all models share similar foundation for exploring the person's needs and abilities, the environment, and the activities for which technology is required, and they also share the same ultimate goal: to identify the best technologies that will match the person's needs for improving the quality of life in all aspects. Similarities and differences of the models indicate the need for effective assistive technology assessment that will lead to the choice of technology that builds on the strengths of the person in their various environments and responds to challenges by

increasing opportunities. Hence, current literature calls for the need of a holistic assessment that at the same time can lead professionals involved to considerations beyond the sensorimotor and cognitive aspects of the access assessment toward language function and interaction (Kay 2014), as well as toward pedagogy and inclusion (Hersh 2010). Thus, collaboration, teamwork, and sharing of knowledge and experience in multidisciplinary teams (Copley and Ziviani 2005, 2007; Borgestig et al. 2013) are vital. This collaboration allows users', rehabilitation professionals', educators', and family's teams to get involved in dialogues (Watts et al. 2004) toward user-centered informed decisions in order to match the choice of both the model and the technology to the person's needs in all sectors of life and activity.

In the following section an example of a research case study of a person with physical disabilities and complex communication needs is briefly presented, demonstrating the implementation of the previously discussed technology features and models.

Example of a Research Case Study

This case study is part of a broader longitudinal qualitative research that involved several cases of persons with physical disabilities who use assistive technology (Mavrou 2011a). The present example describes the case study of a young man with cerebral palsy, during which data was collected through participatory observation, interviews, and document analysis in order to map assistive technology provisions and services in Cyprus and in attempt to understand, improve, and reform practice in relation to AT interventions. The participant is diagnosed with cerebral palsy (spastic quadriplegia), with no verbal communication and with no additional sensory or intellectual disabilities. Due to his physical disabilities and profound difficulties in verbal communication, he attended a special education unit in the mainstream school, in both primary and secondary education, until adolescence educators and professionals had difficulty to define his

intellectual and cognitive abilities. His communication was restricted to yes/no questions, to which he was responding with eyes and head movement.

The first assessment for assistive technology provision was conducted in lower secondary education. Following the basic principles of the SETT model (Zabala 2005), the first assessment identified the physical access to a digital communication device as the student's main functional area of concern, taking into consideration his age and interests; the need to move around in school environment with the aid of support staff (no electric wheelchair); and communication and participation in specific school curriculum subjects as the main tasks required for active involvement. Given the resources available at the time (in the public sector), a laptop computer with switch-accessible software (Clicker5) and a large-size switch with wireless adaptor were suggested as the main technology tools (Mavrou 2016).

Nevertheless, as the participant's communicative needs and abilities increased, the equipment proved ineffective. The use of the switch and scanning demanded increased physical effort by the user and entailed the risk of AT abandonment (Seymour 2005). Hence in 2 years' time, the AT specialist requested a reassessment, which was now conducted with mixed-models approach. These involved the basic principles of HAAT (Cook et al. 2008), especially for identifying the best approach to human device interaction, regarding physical accessibility, the pedagogical aspect of CAT (Hersh and Johnson 2008a, b) in order to match the needs of the participant in terms of inclusive education, and the MPT (Scherer 2005), to best determine environmental and other factors/barriers that affected the use of technology in various settings. Thus, a new long-term assessment process followed, which involved close collaboration and teamwork among the user, family members, the physiotherapist, the school technology teacher, and the assistive technology specialist. The ultimate goal identified was the use of high-tech AAC for the participant's independent communication and learning experiences, with a technology that would reduce the physical effort load needed. Thus, in terms of

control interface, the eye control (eye-gaze technology) was identified as the most appropriate for physical access, which is one of the reasons that long-term piloting, training, and adaptations were necessary (Borgestig et al. 2016). Eye control was considered to provide independence to the user for controlling his communication device, with direct selection as *selection method*. In addition, a grid-based augmentative and alternative communication software (The Grid 2) supported with Widgit symbols (localized in Greek) was chosen as a suitable *selection set*. Along with the matching of technology with the participant's needs and competencies, other configurations were made including sitting and position, mounting of the AAC device, and continuous adaptations of the selection set.

Following a collaborative consultation intervention model (Borgestig et al. 2013), the participant was able to develop excellent digital skills in very short time and to become a very effective eye-gaze user of his AAC device for both communication and access to digital technology (Mavrou 2016). In addition, in terms of selection set, he further moved from the use of symbol supported short phrases for AAC to independent symbolized phrases and words and then to gaining literacy and word prediction. Hence, the design of a customized language development program resulted in successful communication competence development (Smith 2015). In a short amount of time, the communication environment for this participant extended to the online environment and to the use of the Internet, email, Skype, and much more (Mavrou 2011b), leading to the integration of AAC out of a narrow set of contexts (Smith and Connolly 2008).

Though this case study resulted to a story of success, the whole process and intervention was long term, with a number of barriers in course and a number of difficulties that both the participant and the support team needed to overcome. These involved continuous access to technology during assessment and trials, funding, and resources that were not available on time, training of professionals and family members, as well as follow-up guidance and support (Mavrou 2011a).

Conclusion

The potentials of the rapid technological advances and the impact of assistive technology in the lives of people with disabilities are highly acknowledged and discussed in the relevant literature through the years (Abbott 2007; Hersh 2010; Borgestig et al. 2013; Mavrou et al. 2017). Research provides evidence for the role of technology, as well as the barriers and opportunities (Lazar and Jaeger 2011; Mavrou 2011a; Layton 2012) for its implementation in education and learning (e.g., Alper and Raharinirina 2006; Standen et al. 2011; O'Malley et al. 2013), in employment (e.g., Wehmeyer et al. 2006; Beyer 2012), in daily life activities (e.g., Schlieder et al. 2013), and in communication (e.g., Clarke and Kirton 2003; Light and Macnaughton 2014). Often, the design, development, and use of (assistive) technology for people with physical disabilities may encounter more challenges, particularly in the case of multiple disabilities with the combination of physical limitations and other sensory, cognitive, and/or communication difficulties (Veigl et al. 2017). A quite significant percentage of people with physical disabilities, especially those who are nonverbal, become less involved in activities, and they tend to have limited opportunities for interaction, learning, and participation (Mavrou 2011a; Angelo 2000; Borgestig et al. 2016).

While assistive technology can provide opportunities for independence, in order to increase motivation and activity involvement, for people with physical disabilities, there are a number of factors that affect AT's effective implementation. A holistic approach to AT assessment (Kay 2014) is important, which may derive elements from the principles of various different frameworks. When (complex) physical limitations are in place, the use of AT is highly determined by the way the dynamic interaction between the person, the technology, and the activity (Cook et al. 2008) is supported, improved, and sustained. Hence, the role of teamwork and multidisciplinary (Copley and Ziviani 2007; Borgestig et al. 2013), as well as the different perspectives that the various AT

frameworks provide for each of these elements (person, activity, environment, technology) (Watts et al. 2004), should go beyond the assessment process. Thus, collaborative and multi-dimensional approaches are fundamental for continuous access to AT tools, training, guidance, technical support, and mostly opportunities for implementation in multiple contexts.

It is evident that current and future research and development trends in technologies for people with physical disabilities have already turned toward user-centered designs and participatory action research (Dorrington et al. 2016; Veigl et al. 2017), as well as the investigation of the potentials of new mainstream technologies (e.g., mobile and Internet technologies) (Abbott and McBride 2014) and robotics (e.g., Cruz et al. 2017). Nevertheless, the collective effort for the successful implementation of technology for people with physical and other disabilities and the critical elaboration on research evidence should also be put forward by policy recommendations and policy making, with inputs from many high-level experts.

The use of assistive technology and accessibility is endorsed by the UN Convention for the Rights of People with Disabilities (Convention on the Rights of Persons with Disabilities (CRPD), available at: <https://www.un.org/development/desa/disabilities/convention-on-the-rights-of-persons-with-disabilities.html>). Hence, no state can disregard the importance of assistive technology service delivery systems in health, social care, and educational sectors. It is therefore suggested that future research should look into new ways of collaboration among all stakeholders at national and international level, including the industry, the academia, governments, as well as international alliances and umbrella associations (e.g., the EU, the UN, the WHO, etc.).

Introduction

Over the past three decades, a great number of technological implications have been disseminated and applied toward communication, workplace, education, and life of individuals with vision impairment (i.e., those who are blind or have low vision). It is evident that many types of technology, such as assistive technology, augmentative technology, communication technologies, and/or alternative technologies, have influenced and enhanced the quality of life of people with vision impairment through supporting mobility, transport, health, and education (i.e., instructional practices and curricula). These technologies have contributed significantly to modifications of instructional methods and teaching strategies in the education of students with vision impairment (Gerber 2003).

In fact, technology and assistive devices allow individuals who are visually impaired to have access to a range of materials through a variety of different medium ranging from electronic to printed material. In our information-based society, this appears to be an unlimited capability and provides unprecedented educational and vocational opportunities for people with vision impairment (Cooper and Nichols 2007; Kerscher 2001).

Undoubtedly, assistive technology offers many advantages to people with vision impairment. Screen readers with speech outputs, optical character recognition devices, refreshable braille displays, electronic notetakers, and closed circuit television devices make feasible blind (or visually impaired) persons' accessibility to a vast amount and range of information (Cain and Merrill 2001). This new "era" was already been highlighted by the American Printing House for the Blind (APH 2008) mentioning in their annual report that assistive technology and its applications play a crucial role for 83.6% of students with vision impairment. According to the Individuals with Disabilities Education Act (IDEA):

"an assistive technology device refers to any item, piece of equipment, or product system, whether acquired commercially, modified, or customized, that is used to increase, maintain, or improve functional capabilities of individuals with disabilities" whereas the term "assistive technology service is

defined as any service that directly assists an individual with a disability in the selection, acquisition, or use of an assistive technology device." (Luxton 1990; Parette and McMahan 2002; Presley and D'Andrea 2008)

Definition, Types, and Characteristics of Vision Impairment

Normal sight has a measure of 6/6 visual acuity on the Snellen test chart which consists of letters, numbers, or pictures arranged in rows of different sizes (Mason 1997). This though has now been overtaken by using the more accurate LogMAR scores (<https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2814576/>). Visual acuity also is represented as 20/20 or 60/60 (Snellen) or by 0.0 LogMAR. Thus, if a 6 m-size letter can be read at a distance of 6 m, the normal eye has an acuity of 6/6 or if a child has a visual acuity of 6/36 in one eye, it means that what a normal eye sees at 36 m, the person with the vision impairment could only see at 6 m.

This classification about the degrees of visual acuity was defined by the World Health Organization (WHO) and is widely accepted. According to WHO, children with a visual acuity of 6/18 to 3/60 are considered "partially sighted," and those whose visual acuity is less than 3/60 are considered "educationally blind." Another parameter, which is important regarding vision, is the ability to perceive objects distinctly at distance usually measured at 20 feet (distance vision, Scholl 1986). The Snellen test still remains one of the most common methods of assessing distance acuity internationally which consists of letters, numbers, or pictures arranged in rows of different sizes (Mason 1995). On the other hand, near vision acuity concerns types of close work. It is used in tasks such as reading, writing, and drawing. The procedure of testing near vision usually is associated with reading print of different sizes. Each print size is given an N number; the larger the number, the larger the print (Mason 1995). It expresses the ability to perceive distinctly objects at normal reading distance or about 14 inches from the eyes (Scholl 1986). This classification was significantly modified for the first time,

though not superseded, by a final draft of WHO (1999 version).

There are three main sites of the causes of vision impairment, which may result in a clinical acuity measure. For example, vision impairment may result from some form of ocular damage or damage to the optic nerve, and increasingly vision impairment may be as a result of damage to the brain visual pathway sometimes referred to as cerebral visual impairment (Lueck and Dutton 2015). All of these cases requires special educational arrangements (Mason 1997), but before examining the profile of children with vision impairments, there is need to ascertain what exactly it is meant by vision impairment and how it is measured. The term “visual acuity” was introduced by Donders in 1862 to describe “sharpness” of vision, although nowadays it is the ability to resolve fine detail and, specifically, to read small high contrast letters. Visual acuity is therefore the best direct vision that can be obtained, with appropriate spectacle correction if necessary, with each eye separately or with both eyes (Thomson 2005).

In a formal clinical setting, the standard measure of visual acuity is usually assessed through the “Snellen” notation. The “Snellen acuity” uses letter recognition on a Snellen vision chart. If another test is used to measure acuity, it will often have a Snellen equivalent since this is most easily interpreted vision scoring method.

The Snellen chart, although it is universally accepted, does have its flaws (McGraw et al. 1995). For example, the limited number of letters at the top of the chart does put people with very poor visual acuity at a disadvantage compared to those with better acuity. There is also the problem of irregular progression of letter sizes within the Snellen chart. The jump in difference between the letters representing acuities of 6/5 to 6/6 is an increase of 120%, whereas the difference from 6/36 to 6/60 is 167%. As Thomson (2005, p. 57) states “this is analogous to a ruler which is marked with different length graduations.”

Bailey and Lovie (1976) charts, which negated some of the disadvantages of the Snellen chart, are now being introduced. The Bailey-Lovie charts convert a geometric sequence of letter sizes to a linear scale and give a LogMAR notation of vision

loss. LogMAR vision testing offers a consistent and scientific method of recording vision scores. Although LogMAR is seen as the gold standard in measuring visual acuity, it is still common parlance to use the Snellen notation and to convert it using similar table. However due to the reasons just explained, these conversions are only approximate, and good practice dictates that comparisons between LogMAR and Snellen should not be made.

A more analytical spectrum in the classification of vision impairment is the WHO International Classification of Disease and Related Health Problems (ICD) Version 10 (2016) although as Ravenscroft 2017 has highlighted, cerebral visual impairment is not listed within ICD 10 coding system. In addition to the above classification, the element of visual functioning is equally highlighted by the Resolution of the International Council of Ophthalmology (<http://www.icoph.org/downloads/visualstandardsreport.pdf>) and the Recommendations of the WHO Consultation on “Development of Standards for Characterization of Vision and Visual Functioning (2003).”

It is interesting to present the recent key facts addressed by WHO (<http://www.who.int/mediacentre/factsheets/fs282/en/>) because it provides a global overview of the present situation regarding the population of individuals with vision impairments (VI).

- 285 million people are estimated to be visually impaired worldwide: 39 million are blind and 246 have low vision.
- About 90% of the world’s visually impaired live in low-income settings.
- 82% of people living with blindness are aged 50 and above.
- Globally, uncorrected refractive errors are the main cause of moderate and severe vision impairment; cataracts remain the leading cause of blindness in middle- and low-income countries.
- The number of people visually impaired from infectious diseases has reduced in the last 20 years according to global estimates work.
- 80% of all vision impairment can be prevented or cured (cited from <http://www.who.int/mediacentre/factsheets/fs282/en/>).

In conclusion, there are many differences among people who have severe VI. They are a heterogeneous group with a wide range of educational, developmental, and physical abilities and needs, which require specialized supports and services (Candlin 2003; Huebner 2000; Scholl 1986). The element of heterogeneity is reinforced by the fact that even when two individuals have exactly the same degree of vision loss, they may have tremendous differences because the way in which an individual uses whatever vision he or she has is unique (e.g., individual characteristics of people with vision impairment, vision loss, low vision, chronological age of visual loss). It is the so-called functional vision and plays crucial role in all aspects of life (Best 1992; Corn et al. 2000).

Assistive Technology and People with Vision Impairment: Challenging Limitations

When the person has a residual vision and can use his/her functional vision, then there are specifically designed technologies to meet the needs of those with vision impairment and maximize their residual vision. The vast majority of computers, for example, have accessibility features, such as magnification and speech output. Nowadays, many persons who have vision impairment (low vision) use computers, and they need a combined set of settings, devices, and software to facilitate their functional vision. For example, large monitors (21-inch screen) with accessibility features such as a built-in magnifier and contrast enhancement settings are common. Computer programs such as ZoomText can be downloaded to allow for an even greater range of magnification and contrast enhancement (http://www.aisquared.com/docs/zt2018/ZoomText_2018_User_Guide_English_UK.pdf).

The Multidimensional Function of Screen Access

Access to screen is made feasible through two different functions: (A) amplifying visual information through magnification and (B) translating

or transforming the visual information into alternative sensory information (sound such as speech outputs or touch such as braille).

High-Tech Optical Devices

Optical magnifiers have been the backbone of visual rehabilitation for many years and nowadays are enriched by high-technological optical devices bringing impressive outcomes regarding reading and clarity in image recognition (Virgili et al. 2013). There are near vision devices such as hand-held magnifiers and spectacle-mounted magnifiers. The baseline of these devices is usually twofold: (a) improved lighting and (b) contrast. On the other hand, there are the distance vision devices, such as handheld monoculars (one telescope) and bioptic telescope systems (two telescopes). The aforementioned implementations often include a zoom function, brightness and contrast controls, and color inversion. In essence, the above technological implementations fall under the umbrella of the computing process of magnification (Corn et al. 2000).

Closed Circuit Television (CCTV)

These devices, closed circuit television systems, are considered to be the “ancestors” of electronic magnification and contrast in the contemporary history of assistive technology for people who have residual vision. Two strands can be distinguished regarding these devices: (a) desktop CCTVs and (b) portable CCTVs.

Desktop CCTVs were the “groundbreakers” in electronic magnification and constitute the pillars for the systems that are used today. Flat screens are used, and apart from the traditional black and white contrast technologies, all up-to-date CCTVs have expanded this capacity into offering all the colors and saturations in order to design a great variety of contrast settings (Bennett 1997; Markowitz 2006). In addition, many models have cameras whose focus can be adapted for distance viewing and optical character recognition (OCR). These capacities enable the person with vision disability to read a page because the camera takes the photo, the OCR in turn converts the letters on the screen, and hence the user can read the page adjusting the magnification and contrast

or listen to a computerized voice that reads aloud text on the screen (Holbrook and Koenig 2000).

Portable CCTVs have the same properties as the desktop CCTVs plus the property of portability, which give users the freedom to travel or work away from their home desk system. Some of the more common units available are the Zoomax Snow and Zoomax HD 7, Pebble HD preis from Enhanced Vision, SmartLux Digital Portable Magnifier from Eschenbach, and Ruby from Freedom Scientific.

B. Translating or Transforming the Visual Information into Alternative Sensory Information.

This path of alternative sensory information needs at least two types of specialized software, which are usually embedded in computers, tablets, or smartphones. One is reading the text, namely, a screen reader, and the other one serves as a speech synthesizer. A screen reader “reads” what is displayed. In essence, a screen reader is software that is now commonly pre-installed in PCs, tablets, phones, etc., which reads aloud the text that appears on screen, such as documents, menus, icons, web pages, dialog boxes, phone numbers. The screen reader interprets the text on the screen (either on computer screen or on mobile phone) and uses electrical signals to activate the synthetic speech (Sherwin 2015). Through this software, people with vision impairment can access Internet resources, all texts contained in files, digital libraries, email, forums, etc. Some popular representatives regarding screen readers may be “JAWS” of Freedom Scientific (<http://www.freedomscientific.com/products/fs/jaws-product-page.asp>), “Windows Eyes” of GW Micro (<http://www.gwmicro.com/Window-Eyes/>), “SuperNova” of Dolphin (<http://www.yourdolphin.com/productdetail.asp?id=1>), or “VoiceOver” of Apple products (<http://macfortheblind.com/What-is-VoiceOver>) and the like. All the above apps or software provide speech output and screen magnification as well as refreshable braille displays can be connected and used.

The general term which encapsulates the process of transformation from visual format into aural format is called text-to-speech (TtS) technology (Dutoit 1997). Through this technology,

digital text is rendered aloud conveying all the meta-data of the text (i.e., lists, bold, italic, etc.; see Argyropoulos et al. 2015). The TtS can be used as stand-alone software, be built-in applications or operational systems, and be embedded in screen readers. TtS is much more effective than human narration, because the latter is time-consuming and requires much cost and effort (Peters and Bell 2007).

Sometimes the output may not only be speech but a tactile format such as a braille display. Through a specialized software, the system converts the content into braille characters. To transform the content into braille, an electronic refreshable braille display is needed which is hardware and is usually attached to the computer and driven by a specialized software. This particular braille display consists of a series of six- or eight-dot braille cells made up of small metal or plastic pins arranged in a rectangular context. The pins are raised and lowered depending on the electric signals, which are created due to the piezo effect of some crystals, whereby they expand when a voltage is applied to them. Each crystal is connected to a lever, which in turn raises the dot from a braille cell (Quick 2010).

Finally, the output may be a combination of tactile and aural stimuli. For example, technologies known as accessible pedestrian signals (APS) aim to assist people with vision impairment to cross streets through tactile arrows and audible signals. For example, poles with crosswalk buttons are placed within specified distances of the curb and crosswalk, and pushbuttons (the buttons used to request a walk signal) are placed on the side of the pole closest to the corresponding crosswalk (Carter et al. 2007).

Wearable Technological Devices

As mentioned above, the underpinning qualities that are essential for any technological implementation (software or hardware) regarding individuals with vision impairment are pertinent (a) to enhancing visual information via a variety of methods and techniques and (b) to transforming visual information into alternative sensory information, such as sound or touch. Another branch of assistive technology relevant to the above

qualities and related to ubiquitous computing (Velázquez 2010) is modern wearable technology. Wearable technological devices make technology pervasive by incorporating them into daily life. Devices worn on many parts of the body – such as the finger, hands, wrist, tongue, head, chest, abdomen, and feet – have been designed and tested over the last decades to provide wearable solutions to the problems of reading and mobility when it comes to navigation (i.e., indoors navigation, outdoors navigation) (Ramadhan 2018; Tsukada and Yasumrua 2004; Velazquez et al. 2009). In all the aforementioned devices, there are common patterns but differences as well. For example, outdoor navigational apps are usually designed differently than apps for navigation indoors because the former includes a GPS system, whereas this is not the case for the latter (indoor environments always change their reference points; therefore there have no stable structure over time).

Electronic eyeglasses constitute excellent example of wearable devices for improving vision (such as read books, distinguish street signs and objects from far away, and know what friends' and relatives' faces actually look like). Each of these electronic eyeglasses houses a high-speed, high-definition camera that captures what the user is looking at. The device through a series of algorithms enhances the video input and in turn displays the video through appropriate screens in front of the user's eyes (or even through auditory input). The cameras in real time enhance the footage that beams across two screens, one in front of each eye (Hwang and Peli 2014). In addition, a magnification process takes place combined with contrast. Lastly, as a wearable device, there is the capacity of a hands-free operation, which is of great importance for people who have significant vision loss, even up to 20/200 vision.

OrCam My Eye wearable technology, for example, constitutes an integrated portable device with smart camera reassigned to help individuals with vision impairment. The camera is attached to the glasses of the person who is visually impaired and transmits information converting the visual information into an auditory format in real time.

Labels, documents, banknotes, products, and other images, including faces and names, can be quickly and efficiently converted into spoken words. The device has multiple readable features that are compatible with headphones and speakers as well (<https://www.orcam.com/en/myeye2/>).

Mobile Technological Devices

Mobile assistive technologies constitute another platform for conveying and transforming information through accessible formats. Similarly, as it happens in wearable technological devices, smartphones and tablets – the main representatives of mobile assistive technologies – are now produced with accessibility options to allow magnification or contrast enhancement (Hakobyan et al. 2013). Many of the apps developed in mobile technological devices, which aim to support people with vision impairments fall roughly into three categories:

- (a) Navigation: Global Positioning Systems provide the person with vision impairment auditory instructions to streets and intersections, business names and addresses, public transportation or schedule appointments, and web searches (Chandana and Hemantha 2014).
- (b) Identification: specialized detectors provide the person with vision impairment feedback about the color of clothes, currency identification, products in supermarkets, and so on (Hild and Cheng 2014; Sangami et al. 2015).
- (c) Reading: text readers and barcode scanners provide the person with vision impairment audible formats or enhanced images (screen reader or screen magnification) to have access in large databases, such as national libraries, or in vast repository containing nearly every work of literature available in the public domain (such as the Project Gutenberg – Free ebooks, <http://www.gutenberg.org/>).

All the above share the same operation principle: they all scan the environment – using different technologies – and display the information gathered to other sense (mainly hearing and touch) (Velázquez 2010). Specifically, the

wearable systems are considered to be of high importance because they leave the users' hands free increasing in this way his/her degrees of independence and mobility.

Other Computer-Based Assistive Technology

Braille Embossers

These devices are hardware, which started to print text documents in the form of braille text. They use specialized software to convert text to braille. The evolution of the embossers continues to become more and more sophisticated, leading to new developed software applications, which in turn result in better-raised and recognizable dot tactile graphics. Nowadays, tactile graphics can be produced simultaneously with the braille text in the same hard copy sheet and by the same braille embosser (Kouroupetroglou et al. 2016).

Electronic Notetakers

Electronic notetakers are portable devices equipped with a speech synthesizer, a braille display, and a braille or typewriter keyboard. They are extremely useful in storing information, keeping track of appointments, and taking notes. They can be connected to braille or laser printers, and the latest electronic models of notetakers provide advanced word processing, web browsing, and other functions (Kapperman and Sticken 2000).

Specialized Keyboards

Users with vision impairment may benefit from keyboards with a high-contrast key legend or from the addition of high-contrast labels. Also, large key keyboards (with high-contrast lettering or color-coded keys) may enhance the residual vision of people with vision impairment and enable them to be efficient at work or at home (<https://www.techsilver.co.uk/large-print-keyboard-best/>).

Other Emerging Breakthrough Assistive Technology

In general, emerging technologies are characterized by radical novelty (i.e., have the capacity at least to challenge the status quo), relatively fast

growth, coherence, prominent impact, as well as uncertainty and ambiguity (Rotolo et al. 2015). Transforming emerging technology into assistive technology provision requires an ongoing effort, which includes collaboration with people with disability and discussing goals, needs, and functional links between capabilities offered by new technology and functional capacities of the person. One example of such innovative and breakthrough assistive technology for people with vision disability is the iBeacons protocols. These implementations constitute a special class of Bluetooth low energy devices that broadcast their identifier to nearby portable electronic devices. This technology enables smartphones, tablets, and other devices to perform actions when in close proximity to an iBeacon. Hence, people with vision disability through iBeacons can identify shelves in a supermarket, rooms in a campus or in a hotel, streets, areas, or points of interest (Stinson 2015).

Ultrasonic technological implementations in conjunction with Global Positioning Systems constitute up-to-date navigation systems where people with vision disability can detect obstacles and nearby vehicles, identify a place, provide information about traffic conditions and suggest alternative directions, monitor a direction, and/or cross-reference with other streets (Shahu and Shinko 2017).

In addition, high-tech learning spaces equipped with differentiated learning platforms seem to accommodate the changing dynamics of current education in order to meet at a global level all persons' educational needs including those who have vision impairments by appropriate hardware and software. The aim here is to promote web-accessibility and to provide differentiated e-content to learners with vision impairment and in the end enable them to learn and progress in an autonomous way (Kishore and Raghunath 2015; Ramakrishnan et al. 2017).

Finally, the use of robotics at the service of assisting people of vision impairment has been gaining ground in recent years. Indoor navigation involving multipurpose robots seems to prevail in human-robot interaction, and robot hardware

learning environment has already been embedded in educational practice and application (Marques et al. 2017).

This entry has not covered new technologies in bionic eye development, as while this could be seen as the latest advancement in assistive technology, it has been excluded as the technology is not yet available to all who need it while those described above are all available through the open market.

Conclusions

As mentioned above assistive technology, devices, and services have been developed to “increase, maintain, or improve functional capabilities of individuals.” In specific, there are different types of access such as the physical access, sensory, intellectual, emotional/attitudinal, financial, cultural, digital access, etc. (Dodd and Sandell 1998), and hence there are corresponding technological implementations which enhance and/or facilitate this accessibility. Regarding individuals with vision disability, all barriers have a common denominator (i.e., access to information in general) and significant differences as mentioned above about heterogeneity. For this reason, there is a big range of technological devices and services which are embedded in a bigger network including the person with the vision impairment (i.e., user), specific implementation(s) of relevant assistive technology, and the activity in conjunction with the environment in which it is being used (e.g., home, workplace, leisure).

Because of the universal design, there is a trend that the accessibility is not depended on the visual acuity of the person; rather the advances and all technological implementations are based on relatively new approaches and theories such as universal design or universal design for learning (Follette 2001). This means that the evolvement in technology resides more on a global basis of “thinking” and design rather than on specific needs. The needs of a person with vision impairment may change over time just as the site of vision impairment has, and as a consequence of this, a technological device should be adaptable,

up to date, and flexible to the person’s needs (Stephanidis et al. 1998).

People with vision impairment should be systematically trained in using assistive technology devices and software, by specialist professionals who have the expertise to properly exploit the technology (Guerette 2014). Furthermore, students/people must be assessed before trained in order to choose the assistive technology equipment that is suitable for them. The ultimate goal of assessment should be the selection of a device or equipment that meets the student’s needs. Technological advances should be conducive to blind students/peoples’ development, and assistive technology should be considered as an educational tool and not as an educational end (Abner and Lahm 2002). This is to say that assistive technology should be adapted in the schooling of students with vision impairments as indispensable means, promoting their literacy skills and enhancing their access to the full curriculum.

Anything that prevents or limits the inclusion and active participation of people with disabilities to social life constitute barriers. The accessibility of the common resources of the community (facilities, services and products related to housing, health and rehabilitation, education and vocational training, work, politics, sports) for the use of people with disabilities in conjunction to social awareness represents the essence of an open society (Male 2003; Ravenscroft 2016). The scope of the strategy sustains the increase of quality of life of people with disabilities in respect with independence, security, dignity, decision, and personal responsibility. With such advances in technology, people with disabilities – especially those with vision impairment – now have more options to visually enhance their daily lives and maintain independence.

Assisting Students with Attention Deficit Disorder Through Technology

Eleni Didaskalou

Department of Special Education, University of Thessaly, Volos, Greece

Synonyms

Computer-based instruction; Students with ADHD-related difficulties; Technology-aided attention training; Technology-aided self-regulation training

Introduction

Identified as the most common disability in childhood and adolescence, attention deficit hyperactivity disorder (ADHD) is characterized by developmentally inappropriate levels of inattention, impulsivity, and hyperactivity (Barkley 2014). The prevalence rates of this high-incidence and neurologically based disability range from 5% (APA 2013) to 11% (Ogg et al. 2015) with increasing rates being reported in recent years. The diagnostic criteria for ADHD involve persistent and severe difficulties in the aforementioned areas, the onset of which occurs in childhood and persists into adulthood (Steiner et al. 2011). However, variations exist with respect to the nature and severity of the difficulties experienced by young people with ADHD across developmental phases and also between sexes (Ogg et al. 2015).

Young people with ADHD often face functional limitations in their academic and social skills that cumulatively lead to diminished learning motivation, difficulties in completing academic work, and problems in developing positive interpersonal interactions with peers and adults (Barkley 2014; DuPaul et al. 2011; Lewandowski et al. 2016; Ogg et al. 2015; Polderman et al. 2010). Students with attention difficulties often encounter learning problems that hamper their academic progress and as such are more likely to be provided with special education services (Loe and Feldman 2007). These children are also more likely to terminate compulsory schooling early and not pursue post-secondary education (DuPaul and Weyandt 2009). Impaired inhibitory control has been suggested, in theory, to be a core deficit underlying ADHD and is associated with disruptive, off-task, and generally undesirable behavior (e.g., school rules infringements) that often warrants special attention and intervention by teachers (DuPaul et al. 2011). Thus, young people with ADHD are likely to display various emotional and behavioral difficulties (e.g., disobedience, aggressiveness, etc.) that adversely affect their interpersonal relationships and contribute to their social marginalization within schools.

School-based interventions targeting the learning and social needs of young people with ADHD are regarded as key primary support provision

(DuPaul et al. 2011) that fosters their educational and social inclusion in mainstream educational environments. A new era of technological development has opened up ways of providing education to students with ADHD which are expected to facilitate their learning, improve their academic and social performance, and promote their social inclusion in schools. Technological applications and devices have been found to be helpful in securing access to the mainstream curriculum and in accommodating the divergent learning needs of students' with ADHD within mainstream classrooms (Dolan et al. 2005). Digital devices, auxiliary computers, and electronic applications are beneficial for teachers, assisting them in the implementation of approaches tailored to the unique learning and social needs of students with ADHD, thus helping these students overcome the learning barriers they face (Schuck et al. 2016). More specifically, computers, various digital applications, and portable online devices have recently been identified as being promising in supporting the learning process of students with ADHD and facilitating in their training in the areas of attention and self-management skills.

Computer-assisted teaching provides students who experience attention-related problems with various alternative ways of accessing knowledge, which maximize their skills for the assimilation and generalization of new concepts. Accordingly, technology-aided learning can be useful in helping students monitor their attention and on-task behavior, thereby improving their overall academic performance as well as their social behavior in the classroom. However, computer-aided learning, technology-based attention, and self-regulation training used for teaching and assessing students with ADHD in a natural learning environment often produce mixed results, and hence further research is needed to clarify their effectiveness. These issues are briefly discussed below.

Computer-Assisted Instruction and Technology-Aided Learning

Over the past few decades, the use of computer devices, digital platforms, software applications, and hypermedia has proliferated, and they are

increasingly being used to provide learning support to students experiencing attention-related difficulties and ADHD (Fabio and Antonietti 2012; Ok and Kim 2017). Computer-aided teaching provides students with flexible interactive learning environments that enable them to highlight and summarize easily, access vocabulary, and test multiple ways of dealing with mathematical problems (Lewandowski et al. 2015, 2016). Despite its promising potential, research on computer-aided instruction for students with ADHD has been relatively limited (Lewandowski et al. 2016). Yet, the available data showing positive results is challenged by other existing studies that question the overall effectiveness of technology-based teaching for students with ADHD, making it difficult to develop a clear picture and draw conclusions. Therefore, further studies need to be carried out to substantiate the outcomes of technology-based teaching in specific academic areas and skills.

One of the strongest advantages of hypermedia tools is that they present learning concepts in a network structure and through a variety of perceptual channels, thereby facilitating access and encouraging assimilation (Mayer 2001). They facilitate the avoidance of distractions by presenting new concepts in such a way that relationships between these concepts are clearly demonstrated. They allow for increased incentive and learning as a result of the flexibility they provide in allowing students to access new ideas. As indicated in the findings of the experimental study conducted by Fabio and Antonietti (2012) on a sample of Italian adolescents with and without ADHD, the students facing attention problems were receptive and benefitted more when the teaching was presented in a hypertext format compared to conventional teaching. The data revealed that the participants who were exposed to the hypermedia-learning environment performed better in the acquisition and retention phases of learning than the control group. Their evidence is further endorsed by an earlier study demonstrating that computer-aided learning facilitates the development of new ideas and the creation

of links with pre-existing knowledge while minimizing the typical counterproductive behaviors of students with ADHD that undermine their learning outcomes (Solomonidou et al. 2004). Similarly, some other studies have found computer-based teaching to be effective for improving the learning skills and on-task behavior of students with ADHD (Mautone et al. 2005; Rueda et al. 2005; Shalev et al. 2007).

In spite of the positive results pointed out above, researchers highlight some methodological issues that raise concerns over the overall effectiveness of computer-based instruction. These issues are mainly related to the small sample sizes of available studies, the lack of control groups, and the limited sustainability of long-term effects (Lewandowski et al. 2016; Rabiner et al. 2010). For example, Rabiner and his associates (2010) conducted a randomized controlled trial research on the impact of computerized attention training and instruction on first grade American students with attention-related difficulties, including ADHD. Their intervention yielded positive outcomes on learning (e.g., reading fluency) and attention, as documented in the assessment conducted by class teachers. Nevertheless, the effects of the intervention program were of a modest magnitude, and attention improvements were not sustained in the following year. Thus, the researchers argued that interventions targeting the difficulties associated with attention and learning, which are experienced by students with ADHD, are in need of improvement, as is the method of evaluating the outcomes of such interventions.

In addition to the limitations highlighted above, the evidence available points to differential effects of computer-aided teaching on different curriculum subjects suggesting that ADHD students may be more likely to benefit from science and problem-solving teaching as opposed to reading (see for a review Lewandowski et al. 2016).

Some studies highlight the potentially positive results of available IT applications, mobile devices, and software targeting the learning difficulties related to ADHD and the improvement of

the academic skills and on-task behavior of students (Cullen et al. 2013; Mautone et al. 2005; Rabiner et al. 2010). More specifically, mobile devices (e.g., iPad, iPods) have recently gained prominence in education and have become popular tools used to enhance the learning experience of students with ADHD, mainly because of attractive and beneficial features such as touch screens, built-in cameras, Wi-Fi connections, and download capabilities. In today's world, an ever-increasing number of young people have access to mobile devices and are connected to the Internet (Common Sense Media 2011). Despite this, the use of such technology and its impact on students experiencing attention problems have not been thoroughly investigated by relevant research (Douglas et al. 2012). Indeed, available relevant studies often reveal mixed results in terms of the overall effectiveness of technology on improving and maintaining the academic skills of ADHD students (see Lewandowski et al. 2016). Within the context of the limitations outlined above, computer-based learning is anticipated to deliver a better outcome for students with ADHD if integrated as complementary training aimed at developing cognitive skills, such as attention, a skill that students with ADHD usually face major difficulties with.

Technology-Aided Attention Training

The rapidly evolving electronic world has encouraged the construction of various interactive computer-based games and applications that are easy to use and available to children and adolescents with ADHD (MeMotiva game 2013). These digitalized applications usually provide attractive virtual learning environments and platforms that integrate games targeting the development of various cognitive skills (De la Guia et al. 2015). Indeed, there are several digital computer-based game-type exercises available to young people with ADHD that aim to develop their attention, working memory, and task completion skills (e.g., *Home Routines*, *Attention Exercise*, *Play Attention*, *Cogmed*) (see [http://appcrawlr.com/ios-apps/best-apps-adult-](http://appcrawlr.com/ios-apps/best-apps-adult-adhd)

adhd and www.playattention.com and <https://www.cogmed.com>). Nonetheless, many of the available online applications and electronic game programs have not been tested yet, nor have their results been thoroughly evaluated (Lewandowski et al. 2016).

In addition to the abovementioned game programs, computer-based training focusing on attention skills is recommended for young people with ADHD as a means of improving their attention and further developing their thinking and problem-solving skills (Klingberg et al. 2002). Nevertheless, computer-assisted interventions targeting attention, and delivered to students with ADHD, have generally yielded mixed results in terms of their overall effectiveness and long-term sustainability. A case in point is that of Steiner and her associates (2011) who conducted a pilot study to test the results of a computer-based attention training intervention that was delivered to school-aged students with ADHD. Their sample consisted of 41 American middle school students with a formal diagnosis of ADHD and also included a control group. More specifically, of the 41 students participating in the study, 11 were included in the attention training program, with a further 15 serving as a control group and the rest receiving a different intervention. Their intervention program included sessions of auditory and visual exercises of increasing complexity targeting the students' impulsivity and their attention to the tasks presented. The study was carried out over a 4-month period. Once the participants demonstrated attention and achieved goals quickly, they received immediate feedback, and the accumulation of scores allowed them to move on to subsequent levels, which were more demanding. However, the data collected from teachers, parents, and students themselves showed mixed results. Although the parents of the participating students reported positive results regarding attention and other ADHD-related behaviors, their assessments were not consistent with those given by their children or their children's teachers, who did not detect any significant relevant improvements.

In another similar European study, De la Guia and her associates (2015) conducted experimental research to assess the outcomes of a novel interactive multi-device learning system based on a set of collaborative games and targeting the attention skills of young people with ADHD. Their sample comprised 12 Spanish children and adolescents with ADHD aged between 5 and 16 years who were receiving relevant support at a therapeutic clinic. The aforementioned system used software that controlled the interconnection and operation of various integrated computing devices (e.g., laptop, computer, tablet, mobile phone) allowing participants, who, without any prior knowledge of computer use, were able to interact by touching familiar objects. These interconnected devices were programmed to handle the input received from the participants and to indicate whether the task had been performed successfully. This attractive interactive platform encouraged students to develop ownership of the learning environment by manipulating a set of cards displaying images of animals. The participants were asked to indicate the correct set of images that appeared on the screen based on a growing level of difficulty. Once the embedded system reader had recognized the cards, it responded immediately, indicating whether the sequence presented by the students was correct. The evaluation results showed that the participants had demonstrated improved memory and attention and had enjoyed using the application. Nevertheless, as the researchers argue, the sustainability of the outcomes of this intervention and its applicability to larger samples, in particular, those in non-clinical educational settings, are certainly an issue that needs further examination.

As has already been mentioned, in addition to the significant difficulties experienced by young people with ADHD in the areas of academic and cognitive skills, their various counterproductive behaviors may place them at a high risk of social marginalization within education institutions. Consequently, technological applications and devices may be considered to be extremely promising tools in assisting young people to improve their social performance and mitigate the constraints they face in this area. Further, the combination of learning and self-regulatory

interventions is likely to contribute to the long-term maintenance of improvements in the academic and social behavior of the students (DuPaul et al. 2011).

Technology-Aided Self-Regulation Training

Self-management and self-monitoring programs have been among the most popular interventions for young people with various disabilities, including ADHD (Briesch and Chafouleas 2009; Reid et al. 2005). In contrast to the narrowly defined behaviorist approaches that are largely based on the external manipulation of the social environment, self-management programs focus on the learners themselves by encouraging them to monitor and evaluate their own learning and social behavior (DuPaul et al. 2011). Self-monitoring has been identified as a self-management strategy aimed at enhancing students' awareness of their own behavior through recording when a specific behavior has taken place. Typically, at regular intervals students report on their performance using a scale provided. Their teachers also complete a similar scale, and then the student concerned is reinforced depending on whether their assessments match those of the teachers' ratings (DuPaul et al. 2011). Some researchers comment on the positive outcomes of teaching meta-cognitive self-monitoring skills to young people with ADHD, mainly in promoting on-task behavior, academic completion, and work performance (Carter et al. 2011; Gureasko-Moore et al. 2007).

Various types of devices and online applications (e.g., iPod touch, iPad, smartphones) are considered useful in helping students with ADHD to self-monitor their attention and on-task behavior. However, their use in educational settings has not been systematically evaluated by research. Thus, despite the fact that some of the available studies show positive results (Laurice and Elisha 2011; Wills and Mason 2014), these positive effects may be of limited duration and may not be maintained when electronic devices are removed (see Lewandowski et al. 2016).

This is illustrated in the study carried out by Bruhn and her associates (2015). Experimental research was carried out by them to assess the

effects of an iPad application (SCORE IT) designed to assist two American middle school students (one with ADHD) to self-monitor learning as well as disruptive behaviors. This particular application stores the results of monitoring, carried out by the students and their teachers, in the form of scores based on the student's compliance with the rules of the class. These scores are then displayed in chart format at the end of each day. As soon as the participants' goals for each day are met, the students are reinforced by their teachers. The collected data can be stored and examined for up to five consecutive days, thereby allowing students and teachers time to review and track their progress. Although the results showed improvements in the participants' on-task behavior and engagement in learning, these were not sustained in the long run.

In line with the reasoning above, Schuck and her colleagues (2016) conducted a pilot study to test the feasibility of using a web-based application (iSelfControl) that was designed to evaluate student self-control and compliment traditional classroom behavior management approaches. More specifically, the pilot testing included 12 fifth grade American students with ADHD attending a clinical facility where a universal behavior management program had been implemented. Each student had their own iPad, and their application prompted them to evaluate their behavior every 30 min on three behavioral goals, namely, paying attention, following the rules, and behaving appropriately toward others. At the same time, teachers rated the students' behavior on another iPad. The application was designed in such a way that allowed staff to complete entries for many students within a very short time. The students could check their progress charts, on their iPads, throughout the day and receive feedback accordingly. This pilot intervention lasted for six consecutive weeks, and data collected consisted of a total of 141 teacher-student paired observations. The results indicated that by using this particular application, the students' awareness of their behavior improved, as did their ability to regulate their behavior effectively. Despite these positive outcomes, the researchers recommend that these results need to

be further substantiated by complementary studies involving larger samples of students and testing the iSelfControl in natural learning environments (e.g., classrooms).

Conclusions

This entry comments on the use of technology in assisting students with ADHD in their learning and in improving their on-task and social behaviors. In particular, we focused on technology-assisted instruction as well as attention and self-management training, which have been found to ameliorate the difficulties that this particular group of students faces in academic and social settings. Therefore, within this new evolving electronic era in education, computers, mobile devices, and digital platforms appear to be promising tools that may be used in promoting the academic and social skills and performances of students with ADHD. Despite their promising potential, however, we could argue that their application in natural learning environments and schools has not been thoroughly examined by relevant research in the field. Thus, some of the studies available suggest mixed results in terms of overall effectiveness, while others highlight methodological limitations that prevent researchers and practitioners from reaching clear-cut estimations and drawing conclusions.

Nevertheless, one of the strongest advantages of digital applications and electronic devices is that they can respond directly to the complex needs and interests of students and are therefore likely to contribute to providing specialized support within mainstream educational settings. Consequently, available evidence needs to be further substantiated by future studies that involve larger samples of students with ADHD as well as complementary data from natural educational environments, in addition to that collected in clinical settings. Educators and researchers need to work together on the implementation of technology-aided support interventions within mainstream classrooms. Teachers may need guidance from researchers and technology specialists to address the complex needs of ADHD students, as well as

receive training to successfully implement these promising technology-led educational support services.

Assisting Students with Intellectual Disability Through Technology

Intellectual disability

Introduction

Intellectual disability (ID) refers to limitations in intellectual functioning and adaptive behavior, with onset during the developmental period (AAIDD 2018; Papazoglou et al. 2014). Moreover, ID is characterized by heterogeneity in terms of etiology, and it pertains to a variety of behavioral profiles in terms of relative strengths and weaknesses through an array of domains including the cognitive, language, social, and socio-emotional domains (Bertelli et al. 2018).

Over the last decade, there has been an increasing emphasis on adaptive functioning and the consequent support needs of people with ID. In the latest (5th) edition of the *Diagnostic and Statistical Manual of Mental Disorders* (American Psychiatric Association 2013), the severity of ID is specified on the basis of adaptive functioning which is considered indicative of the supports needed by a person with ID (Papazoglou et al. 2014). Even in earlier years, it became evident an increased emphasis on the development of individualized supports to address the unique needs of a person with ID within an inclusive environment, along with the development of relative measurement scales and tools (Thompson et al. 2009). This special emphasis was consistent with a turn toward the social-ecological model of disability (Shogren et al. 2017; World Health Organization 2001), while an even broader modus for viewing, understanding, and addressing intellectual disability has stemmed from the “social and human rights perspective” on disability (Bach 2017).

Within the context of such a broader perspective, a tendency toward more individualized or person-centered support services has been generated in pursuing the enhancement of inclusion and achievement without ignoring at the same time information on the unique challenges related to ID (Bach 2017). Furthermore, the concept of “support” is becoming the central part of interventions and policies that target the promotion of educational, social, community, work, and economic inclusion for people with ID. In this realm of “adequate supports” and “support services” to prevent marginalization and promote active

citizenship, quality of life and self-determination for people with ID, technology has been progressively recognized as a crucial enabler of these goals and of inclusion in general.

Connecting Technology with Support Provision and Inclusion

It is widely acknowledged that technological developments and resources have a catalytic role and effect in almost all aspects of our daily life. In light of this fact, the provision of opportunities for technology use by people with ID is a *sine qua non* situation in order for the modern societies to be considered inclusive; moreover, technology resources are among the critical supports for people with ID as they can assist them, under the appropriate conditions, in achieving independence, participation, and progress into inclusive societies.

In the context of providing personalized supports tailored to each person's with ID needs, strengths, choices, and goals, technology – in terms of devices, tools, systems, and solutions – (Lancioni 2017) can assist people with ID in improving their functioning in a variety of areas related to adaptive behavior, promoting their personal and interpersonal development, and enhancing their participation in school, work, leisure activities, and community (Wehmeyer et al. 2004). In other words and in light of a social-ecological point of view, technology, either instructional/educational or assistive, is considered a crucial part of the supports that should be provided to people with ID on the basis of their individual strengths and support needs to address the contextual/environmental challenges encountered within the school and the community in the course of their participation in inclusive settings in general (Thompson et al. 2016).

Today, there is an increased emphasis on inclusive education and in specific the inclusion of students with ID in general education classrooms (Thompson et al. 2016). Considering possible indicators of quality inclusive education, it has been suggested that they are related, among others, to the promotion of students with disabilities participation, progress, and achievement in

general education contexts and settings and to the implementation of curricula grounded in the principles of universal design for learning (UDL) (Loreman et al. 2014; Ryndak et al. 2014). Moreover, access to and availability of assistive technology are among the critical considerations relating to indicators for the measurement of progress in inclusive education (Loreman et al. 2014). In this vein, the provision of opportunities to use universally designed technology can facilitate all students, including those with ID, in meeting both the structured (i.e., academic) and informal (i.e., social) processes taking place into an inclusive school. Consequently, at the school level, technology could be conceptualized as a pivotal system of support for students with ID, in terms of enabling them through the pathway of their individual strengths to deal with an array of challenges in various key areas such as participation, independence, learning of new skills, academic achievement, and social functioning and inclusion.

A central issue in the process of assisting people with ID to increase their independence and foster inclusion through technology concerns the “means” by which the variety of available technological resources would be actually, purposefully, and fruitfully used by people with ID. This process of resolving the “what, how, and why” challenges – related to the application of technology to the field of ID – is translated into adequate interventions that enhance technology usability, as well as learning, motivation, and success by the students with ID (Lancioni 2017; Thompson et al. 2016). Selecting the appropriate technological solutions for a student with ID in light of a holistic understanding of the interaction between his/her strengths and weaknesses and the environment, without ignoring the user's opinion, and then teaching the student to effectively use these solutions consist important considerations in the process of bridging the gap that usually emerges between availability and actual and effective use of technological devices (Alper and Raharinirina 2006; Thompson et al. 2016; Zabala 2005). An actual turn toward the development of universally designed technological solutions is considered beneficial for all students with ID, and it could

result to positive outcomes in the areas of availability, utility, and usability (Wehmeyer et al. 2008).

Technology Use Benefits in Within-School and Out-of-School Contexts

In the relevant literature, technology use is characterized as instructional or assistive according to the particular purposes that it serves, although these two categories may have overlapping roles (Ayres et al. 2013; Thompson et al. 2016). Instructional technology refers to supporting students with ID toward their progress and skills enhancement in academic areas, and it applies, generally, in teaching of specific skills, while assistive technology aims at helping students to “participate in settings and activities in ways that they otherwise could not” (Thompson et al. 2016, p. 45).

Technology has become a key component of educational programs for all students and also a central consideration in the development of Individualized Education Programs for students with low-incidence disabilities (Lee et al. 2011). There are an increasing number of studies in the field of technology use by students with disabilities, indicating that both assistive and instructional technology solutions can be used in teaching students with ID and supporting them in various domains. Life skills, including daily living and social skills development, improvement of academic performance and engagement, enhancement of communication, and promotion of self-determined behavior, all of which can contribute to the educational, social, and community inclusion, are central to interventions involving technology use by students with ID. Moreover, positive outcomes for adults with ID in the area of employment-related skills and behaviors can be potentially achieved through interventions based on the use of technology devices (Wehmeyer et al. 2006). However, on the grounds of the heterogeneity issue in the field with ID along with the tendency toward the application of UDL principles, there are still suggestions for further

evaluation of educational interventions pertaining to technology use in relation to the abovementioned areas to strengthen their role as evidence-based practices (Bouck and Bone 2018; Wehmeyer et al. 2008).

The application of universal design (UD) principles in designing technology devices, along with an emphasis on cognitive access, can be beneficial for people with ID as regards the functional use of technology in a variety of domains and contexts (Wehmeyer et al. 2004). In their meta-analysis of single-subject design studies, Wehmeyer et al. (2008) examined the degree to which UD features, namely, “equitable use, flexible use, simple and intuitive use, perceptible information, tolerance for error, low physical/cognitive effort, size and space” (p. 23), were identified in the studies with regard to the technology device used. The results indicated that, with the exception of “flexible use,” every other UD feature was reported only in few studies (less than 10%). Nonetheless, it has been suggested that recent advances in the field of assistive technology, including mobile technology, are more likely to have the potential to meet the basic principles of UDL, i.e., “provide multiple means of representation, provide multiple means of engagement, and provide multiple means of action and expression” (Cumming and Draper Rodríguez 2017, p. 165). However, there is still a need for more research evidence with regard to the use of mobile technology in interventions to support students with disabilities across different areas (Cumming and Draper Rodríguez 2017).

Related literature includes numerous studies which demonstrate that educational software can assist students with ID in both academic and everyday skills. Moreover, recent tablet and smartphone devices offer a new user experience both through their mobility (in classroom-centered, outdoor, or home activities) and their multi-touch, direct manipulation interaction (Gunderson et al. 2017; Hetzroni and Banin 2017). This new user experience can have a direct effect on the acceptability and effectiveness of learning applications for students with ID.

With respect to research findings, assistive technology devices and in particular mobile

technology were found to have beneficial effects for students with ID in life skills development and consequently in the domain of independence (Ayres et al. 2013). It should be highlighted though that the notion of independence in relation to technology use can be viewed as a result of both skills (e.g., life skills) acquisition and reduction in external adult help during task completion. For example, in previous studies, self-prompting procedures with video, photographic, and auditory prompts using a personal digital assistant (PDA) were successfully implemented for the instruction of daily living skills, such as cooking and independent pedestrian travel, to high school students with ID (Mechling et al. 2010; Mechling and Seid 2011).

Taken an inclusive perspective, schools are to ensure meaningful opportunities for all students to learn and achieve (Florian et al. 2017). However, students with significant cognitive disabilities (e.g., moderate or severe intellectual disability) still face a high likelihood of placement in separate educational settings than in general, inclusive, education classrooms (Kleinert et al. 2015). Nonetheless, according to research findings, students with ID may have benefits not only in the social domain but also in academic learning within general education classrooms (Hudson et al. 2013). Technology has the potential to support students with ID on their performance, meaningful participation, and engagement in inclusive learning environments. For example, assistive technology solutions and especially the use of augmentative and alternative communication (AAC) systems (e.g., modern devices and applications based on tablet and mobile technologies) by students with ID having limitations in the area of communication are related to both within-school and out-of-school positive outcomes (Davies et al. 2018; Fossett and Mirenda 2007).

In respect of the provision of academic content instruction and the promotion of access to the general curriculum for students with disabilities, including ID, it has been suggested that the utility of advanced mobile technologies could enhance their academic achievement (Ok and Kim 2017). For example, Creech-Galloway et al. (2013) used

a simultaneous prompting procedure and delivered video via a tablet showing real-life situations with applications of the Pythagorean theorem to teach geometry skills to secondary students with ID and specifically the use of the Pythagorean theorem. Furthermore, technology (e.g., speech-to-text) has been utilized to academic skills instruction, such as writing skills, in students with ID (Cannella-Malone et al. 2015). Writing skills have been also taught in the context of promoting independence and functional skills. For example, the implementation of a computer-based instruction package in combination with a teacher-directed forward chaining procedure provided in a small group structure resulted in improved performance in manual spelling of grocery store words for students with ID attending a high school transition program (Purrazzella and Mechling 2013). In another study, written expression in the context of text messaging on a smartphone and in particular the inclusion of specific socially appropriate statements or phrases within text messages was successfully promoted in young adults with ID by involving a robot in the instructional procedure (Pennington et al. 2014).

The recent trend to extend mobile learning applications with augmented reality (AR) features offers additional opportunities for students with ID. AR has the potential to radically change the nature and effectiveness of digital learning material and activities, through a new 3D interactive experience (Reardon et al. 2016; McMahon et al. 2016). Another recent technological development with a clear potential to students with ID refers to educational robotics (ER), through their new interaction and communication capabilities and the facilitation of a stable environment for experimentation, creation, and learning.

To summarize, it is well documented that technology constitutes a promising avenue for supporting students with ID in educational contexts. However, taking into account the rapid advancements in technology, more empirical research evidence is needed on how and whether students and young adults with ID incorporate advanced technology into their lives (or have the opportunities to do so), across a range of contexts including academic tasks and learning, and

everyday living (home, interpersonal, leisure, and community activities).

In the relevant literature pertaining to technology use in people with disabilities, the potential role of technology on decreasing marginalization and assisting students with disabilities to enhance their autonomy is highlighted. In this case, a probably dynamic linkage between technology use and aspects of self-determination may be acknowledged (Ayres et al. 2013). Enabling a student with ID to effectively utilize technology either in academic or nonacademic contexts could have beneficial effects on student's self-determination. For example, previous intervention studies reported a positive impact of the use of microswitch technology on promoting communication skills in students with profound and multiple disabilities and specifically demonstration of responses related to access to preferred stimuli and choice making, both of which are considered aspects of self-determined behavior (Roche et al. 2015). Technology (multimedia) has been also used in promoting self-determination and self-advocacy in secondary students with intellectual and developmental disabilities in the context of enhancing their active participation in the Individualized Education Program and transition planning process (Van Laarhoven-Myers et al. 2016). Furthermore, the results of a previous study have also shown a positive effect on self-determination of an intervention involving technology use that aimed to promote the involvement of students with disabilities, including ID, in transition planning (Wehmeyer et al. 2011).

In light of the above, it could be suggested that technology has promising prospects for the improvement of people with ID functioning, participation, and progress in various domains, including education and everyday life activities. On the grounds of the implementation of inclusive practices, there is an increasing interest in developing strengths-based interventions targeting the effective and meaningful use of technology devices by people with ID on the one hand and on the other in successfully integrating instructional and assistive technology in education in order to promote positive school and post-school outcomes for students with ID.

Conclusions

Quality of life, self-determination, and social inclusion are among the prospective outcomes of supports provisioned for students with ID, and technology is considered as having a substantial role in the process toward their acquisition. However, a critical issue regards the students with ID sufficient training in using assistive technology devices in order to avoid its abandonment or low use (Alper and Raharirina 2006). Training and preparation of students with ID on the use of technology devices should be a substantial part of broader interventions targeting the organization of the decision-making process with regard to the selection of personalized technology supports (Ayres et al. 2013). The cognitive and adaptive behavior characteristics of students with ID and the related heterogeneity call for interdisciplinary teamwork involving the collaboration between experts in the field of ID, psychology, education and those with expertise on technical issues (Lancioni 2017; Wehmeyer et al. 2004). Nonetheless, the preferences of the students with ID should be a vital consideration during the development of assistive technology services and interventions (Taber-Doughty et al. 2008). On the other hand, rapid technological advancement induces a need for the school staff, practitioners, and professionals in the field of ID to pursue professional development on technology supports for people with ID (Ayres et al. 2013).

Technology seems to be quite promising in offering benefits to students with ID in terms of learning opportunities and educational and societal inclusion. However, there are critical challenges that need to be effectively addressed pertaining to the quality of technology supports, such as solutions tailored to individual needs and strengths in relation to environmental characteristics, and quality of technology usage, such as student's and teacher's knowledge, instruction, and positive experiences in using technology tools (Thompson et al. 2016).

Within an inclusive society, it is imperative to provide appropriate supports to people with ID to enhance their independence and quality of life, and within this context, technology constitutes a

promising pathway to this end. However, it is also imperative to assess and consider the experiences of people with ID by hearing their “voices” and asking for their opinion, besides preferences, on the perceived personal and social outcomes of technology use, and on the perceived parameters that could make more fruitful to themselves the use of technology and enhance their positive personal and social experiences as well (Tanis et al. 2012). Technology could be used as a vehicle for accomplishing such a perspective, since it may provide to people with ID opportunities not only to learn and achieve in a variety of fields but also to express themselves through various solutions.

Within inclusive settings, multimodal systems and material, including low- and high-tech solutions, should be available and used in combination with evidence-based instructional strategies to enhance active learning and engagement of students with ID in academic content (Hudson et al. 2013). The utility of advanced technology devices, especially mobile technology solutions (e.g., tablets), has opened new perspectives in supporting students with ID. The effective and appropriate use of mobile technology can be beneficial to students with ID in terms of educational, personal, and social goals and is considered a potential way of developing more inclusive classroom environments, promoting students’ participation, independence, and social interactions, increasing learning and self-expression opportunities, and decreasing stigmatization (Burke and Hughes 2018).

The utility of advanced technology on assisting and supporting students with ID is a rapidly evolving research area. Undoubtedly, the relevant findings can inform educational practice and intervention development efforts. In the current literature, a need for further research evidence to shed more light on several challenging issues is highlighted, such as the incorporation of assistive technology into classroom on the basis of UDL principles, the implementation of relevant strategies in inclusive rather than separate education environments, the development of evidence-based strategies and interventions concerning technology use, and the ways to facilitate the

utilization of technology by people with ID in terms of availability and usability (Bouck and Flanagan 2016; Cumming and Draper Rodríguez 2017; Ok and Kim 2017; Wehmeyer et al. 2008).

As discussed in the beginning of the entry, some of the key concepts behind the understanding of ID are *person-environment/context interaction*, *social and human rights perspective*, *social-ecological perspective*, and *strengths-based and personalized supports*. Information and communication technologies (ICT) and industry have identified the objectives of *adaptation* and *personalization* for their applications and services, as a means to meet the demand for a better user experience through technology. The e-learning industry has also adopted the “anyone, anytime, anyplace” motto, to underline the fact that barriers are increasingly overcome through the flexibility offered by technology. At the research level, personalized learning environments, which are capable to adapt to the profile of each individual learner, have been the focus for more than 50 years. The complexity of the problems involved limits the generalization and commercialization of respective results. Nevertheless, the emergence of the *ubiquitous* computing and learning era calls for more inclusive applications, to cater for the diversified usage scenarios of *all* users/students. In the knowledge society, users/learners are expected to access learning applications in different settings, which have profound effects on the understanding of disability. This fact has been acknowledged by the technical literature, as reflected in specifications of the IMS Global Learning Consortium (2004): “The term disability has been re-defined as a mismatch between the needs of the learner and the education offered. It is therefore not a personal trait but an artifact of the relationship between the learner and the learning environment or education delivery. Accessibility, given this re-definition, is the ability of the learning environment to adjust to the needs of all learners.” In this context, it can be expected that future learning applications and services will become progressively more inclusive to cover the needs of potentially *all* users/learners, including students with ID.

History and Definition of Learning Disabilities (LD)

The terms learning difficulties and learning disabilities are usually referred to as LD. The history of LD has been well documented with respect to the nature of particular problems (specific language and reading disorders and the behavioral correlates of brain injury) and the structure of special education at the time; a compelling case was made for the need for a category like LD (Kavale and Forness 1995). It should be noted that given the sensitive nature of this problem, and the wide range of special needs, one must be very careful when applying the definition as inferences could be drawn that could lead to negative results.

The history of LD in Australia has been documented in several studies, including Jenkinson (2007), Elkins (2000), and Rivalland (2000). In fact, the definition of LD that is adopted and accepted in a significant way in this important field is also debated, and according to this analysis, the definition hinges on the following main terms that are used in Australian schools:

- Learning difficulties
- Learning disabilities
- At educational risk
- Special needs

These terms are used to describe children who have difficulties with literacy and numeracy learning.

It should be clear to the reader that the meaning of these terms varies from state to state and from school to school in Australia. In fact, the author came face to face with the main actors of a special school where it was not the protocol to refer to students with learning difficulties as LD students, but instead, these students should be referred to by the term “special needs” students. Although these perceptions may be present, the term that has been universally adopted is LD as it is used globally and refers to students with learning disabilities; it should be noted that in the UK, the term Special Needs Education (SNE) is used

in a formal context to distinguish students with learning difficulties and other disabilities. In some publications, the term “learning disabilities” was used by the Department of Education, Employment Training and Youth Affairs (DETYA 1999) and was also used to classify funding categories for special needs students:

a student, who has been assessed by a person with a relevant qualification, as having intellectual, sensory, physical, social/emotional or multiple impairments to a degree that satisfies the criteria for enrolment in special education services provided by the government of the state or territory in which the student is located. (DETYA 1999, p. 2)

The definition of LD appears to be a little vague, and evidence from previous studies in the literature indicates that the normal mainstream curriculum appears to disadvantage this category of students. The question “What is LD?” has been a long-standing source of controversy, conflict, and crisis. Although research in LD has experienced unprecedented growth and has had significant impact on special education, it remains among the most problematic classifications because of the vagaries and antagonisms surrounding the definition (Shakespeare 2005).

Over time, a number of LD definitions have been proposed, but none had emerged as an unequivocal favorite. Currently the two definitions that dominated this area are the legislative definition found in the Individuals with Disabilities Education Act and the one proposed by the National Joint Committee on Learning Disabilities (NJCLD 1994), a consortium of representatives from organizations interested in LD.

The definition of learning disabilities (LD) is a very strongly debated matter. Organizations, such as the National Joint Committee on Learning Disabilities (NJCLD 1994) in the USA, and Australian government groups, such as MCEETYA (2005), have considered and debated the relevant definition of LD or special needs.

The definition of LD which has been adopted in this entry is the one presented by Kirk (1962) and is quoted here for completeness:

A learning disability refers to retardation, disorder, or delayed development in one or more of the processes of speech, language, reading, writing,

arithmetic or other school subjects resulting from a psychological handicap caused by a possible cerebral dysfunction and/or emotional or behavioural disturbances. It is not the result of mental retardation, sensory deprivation or cultural and instructional factors. (Kirk 1962, p. 263)

An issue that has concerned education authorities around the world is whether students with learning disabilities should receive their education in mainstream classrooms or in some form of special schools. A number of researchers support the view that students with LD require an alternative approach to their learning, while others claim that it is best to integrate these students with mainstream classes (Bulgren 1998; Kavale and Forness 1995). Overall, however, there is considerable evidence to support the existence of special schools to cater for the needs of LD students. These schools often exist on a small amount of funding support from the government; however, they cater for individual differences in a significant way through their own fundraising and budgeting efforts.

In a national Australian study that was conducted in 2000, it was found that particular schools demonstrated their comprehensive curriculum through the integration of ICT (Cormack et al. 2000). One of the schools included in that study was Concord School, Bundoora, Victoria; that school maintained its philosophy and belief that ICT provided a lifelong learning and skills for students with LD.

Early researchers concentrated on the learning difficulties of a single primary area or field like English, Mathematics, or Science. Their work and analysis depended on the identification of some criteria or factors like IQ, which did not adequately demonstrate the full scale of the learning problems and disabilities (Bulgren 1998).

From the early days of computers and technology, teachers and researchers were keen to explore computer-based tools in order to enhance learning outcomes. In particular, some of the computer-based software on dyslexia in the 1980s was developed by people who were closely related to students who suffered from dyslexia. For example, Stanovich (1980) used dyslexic software programs to aid students in this area.

It should be noted that similar software application programs were used in the UK and in particular people with dyslexia were assisted with ICT (Becta 2005). Other computer-based software involved mathematical problem-solving, games, and simulations. The latter is a significant area that involves ongoing research about the way games can stimulate and engage students with learning disabilities.

While these approaches may have provided an environment for work and stimulated the students' own interest, there was insufficient evidence to support that the learning outcomes had improved to a significant extent through these approaches (Newhouse et al. 2002 and Becta 2005). The entry will discuss and compare the participant observations from the special schools, and in particular, it will provide evidence of the impact that games have on self-esteem, engagement, and learning outcomes for LD students.

How Big Is It: Prevalence?

It should be noted that globally, the students with LD (OECD 2005) are a unit of interest for researchers, and in some cases, they appear as a sub-unit (subset) of a larger group of people who are disadvantaged in life – for example, the Australian Indigenous people, the Aborigines. In the UK, the House of Commons Education and Skills Committee, 2005, report summary states that:

In 2005 around 18% of all pupils in school in England were categorised as having some sort of special educational need (SEN) (1.5 million children). Around 3% of all children (250,000) had a statement of SEN and around 1% of all children were in special schools (90,000)—which represents approximately one third of children with statements. With such a large number of children involved, it is important to recognise that many children are receiving the education they need in an appropriate setting. It is equally important, however, to highlight the difficulties faced by a large number of parents for whom the system is failing to meet the needs of their children. (HC: 478 I 2005-06, p. 5)

The Australian literature identified a study by Elkins (2000) where an analysis of learning difficulties and disabilities was reported (Fig. 1). The sections below provide a summary of the

main findings about this important area. The prevalence and identification or reference to special needs is also extracted from a study by Rivalland (2000) (Fig. 2).

The prevalence data were analyzed state by state in Australia in a study by Rivalland (2000) in “Policies and Practices: Students with Literacy Difficulties” case study in Elkins (2000) “Mapping the Territory” vol 1.

What is important here is quoted in the following paragraph from the report by Rivalland:

Assisting Students with Learning Disabilities Through Technology, Fig. 1 Learning difficulties: factors. (Source: Elkins 2000)

The many differences in definition and identification across the systems and sectors make it very difficult to make generalisations about prevalence. However, the case study schools do tend to reflect the findings of the Survey of Schools. Most of the case study schools, like the schools in the survey, reported a range between 10 percent and 30 percent. Many of the case study schools clustered between 15 percent and 25 percent with three schools reporting prevalence data below 15 percent. (Rivalland 2000, p. 51)

The terminology of learning difficulties and learning disabilities is further reflected in a survey (Rivalland 2000, p. 69) where principals referred to these categories by the following percentages listed in Table 1.

The term “learning disabilities” was more likely to be used by teachers with special education training and by school psychologists. The term LD is widely accepted in the psychological field in the USA, but is usually qualified in Australia to specific learning needs.

The definition that has been used for the term LD by MCEETYA (1999) is similar to one from the USA and is provided here to assist the discussion:

A generic term that refers to a heterogeneous group of students who have significant difficulties in the acquisition of literacy and numeracy and who are not covered in the Commonwealth’s definition of a student/child with a disability. . . Learning disability is believed to be a difficulty that is intrinsic to the individual and not a direct result of other conditions or influences. (MCEETYA 1999)

Western Australia	Victoria	New South Wales	South Australia	Queensland
Crestwood (20%)	St Bernadette’s (5%)	Lake Hewitt (25%) estimated by principal	Messiah (13%)	Bennetts Hill (24–25%)

Factor	%
Learning difficulties	47
Children at risk	37
Special needs	17
Learning disabilities	10

Assisting Students with Learning Disabilities Through Technology, Fig. 3 Venn diagram for learning difficulties

Range of Special Needs

Given the complexity of the definition of learning difficulties, one way to represent these differences is with the following Venn diagram shown in Fig. 3.

The term “learning difficulties” is used to refer to a large group of children who need extra assistance with schooling, while “learning disabilities” refers to students who are a small sub-group who exhibit severe and unexplained problems. In fact, in the USA, it is also referred to as “learning educational disabilities.”

The research presented here originated with an interest in dyslexic students. A federal government report on students with disabilities – “Technology for Learning: Students with Disabilities” – reported 21% prevalence (Cormack et al. 2000). In a study by Miles (2004) in the UK, a number of issues were discussed that might account for the difficulty of assessing the prevalence rate with dyslexia around the world. Among these are the issue of resources to carry out the analysis and dyslexia variants. The prevalence rate varies between 5% and 17% (Wikipedia), and Miles (2004) arrived at the conclusion that

in the UK, there are approximately 4–6% people who are dyslexic. All that can be said with any certainty is that in every English-speaking country, a significant percentage of the population has reading and spelling difficulties varying from mild through to severe. A parliamentary report titled “Helping People with Dyslexia: A National Action Agenda” shows that the prevalence rate across all states in Australia ranged from 5% to 10%. These facts show that the prevalence rate of dyslexia has not changed by a significant amount over the last two to three decades.

Models for Education and Technology for Disability

A starting point in modelling learning with ICT is the Learning Interface Model (Adam et al. 2006) – see Fig. 4. In this model, teaching can be thought of as an interaction between teachers, students, experience, and knowledge (Schunck and Nielsson 2001). How these entities interact can be seen in different teaching/learning paradigms, ranging from one characterized by a verbal flow of information streaming from the teacher directly to the students to the model shown in Fig. 5.

In this model, the teacher acts as a catalyst or consultant for students to show them where information can be obtained from. Next, we can consider the model from Schunck and Nielsson (2001) as a starting point to examine what changes are needed to the traditional teaching model as we move toward the adoption of technologies in the curriculum. These changes are captured in Fig. 6; this is a reproduction of the model in a study reported by Schunck and Nielsson (2001).

From Traditional Teaching and Learning Models to e-Learning

In their study, Schunck and Nielsson (2001) examined three different scenarios to describe pedagogic developments from a historical perspective. These perspectives primarily focused upon the interaction between teachers, students, and given subject matters (domains). In proposing

Assisting Students with Learning Disabilities Through Technology, Fig. 4 Learner Interface Framework – Adapted from Brusilovsky and Papert. (Source: IEFTS 2001)

their model, they considered the following paradigms:

- The paradigm of yesterday*
- The paradigm of today*
- The paradigm of tomorrow*

Naturally, the structure and the developments in the surrounding society as well as the political dimensions play an important role as far as the models' individual lifetime and the transition from one model to another are concerned. The models may be looked upon as changes of paradigms, assuming new forms in connection with the implementation of new discoveries or theories and new decisions or changes in views and attitudes.

Adopting the Schunck and Nielsson e-Learning Model for LD Students

The study adopted the above e-learning paradigm to determine the impact of technology on the educational outcomes of LD students. The model

Assisting Students with Learning Disabilities Through Technology, Fig. 5 Paradigm of yesterday. (Source: Schunck and Nielsson 2001)

in Fig. 7 illustrates the facilitating role of the teacher and the independence of students in working and sharing their knowledge through experiential learning. The early research was

Assisting Students with Learning Disabilities Through Technology, Fig. 6 Paradigm of today. (Source: Schunck and Nielsson 2001)

proposed at Macedon Ranges where this model was applied to the main actors, like the school principal and the IT coordinator. Fortunately, the model was accepted, and the research study was facilitated through the exploration of the policies and infrastructure that was available at the school level.

Technology Enablers and Inhibitors for Disability

Earlier research explored issues regarding both the adoption and impact of ICT in teaching and learning. The main regions that were considered were Australia, the UK, the USA, and Africa. In addition, studies were found from some other countries like Turkey, Nepal, and Malaysia, where technological, political, and socio-technical factors were investigated. The main findings from these studies relate to school leadership, professional development, and perceptions from

parents. In a study by Elliott (2005), the main factors that were identified were in fact divided into two categories, structural and process barriers, and are summarized in Tables 2 and 3.

According to Elliott (2005):

ICTs have not had the widespread impact on teaching and learning processes envisaged a decade or so ago is disappointing but not surprising. Most educational innovation happens slowly and ICT is in itself continually transformed by new developments and market conditions. It is not a discrete subject and its applications in education are the subject of considerable debate, informed by a combination of scholarly discourse, opinion and research. (Elliott 2005, p. 8)

Elliott further provides a summary of the literature for barriers to effective ICT learning in schools. The following are highlighted in several contexts (White 2005), and calls for national ICT standards, greater institutional support and infrastructure, and better professional development for teachers have been addressed to varying degrees in all states and territories.

Assisting Students with Learning Disabilities Through Technology, Fig. 7 Paradigm of tomorrow: the e-learning paradigm. (Source: Schunck and Nielsson 2001)

Assisting Students with Learning Disabilities Through Technology, Table 2 Structural barriers for ICT adoption. (Source: Elliott 2005)

Structural barriers
Limited classroom space
Lack of computers and/or internet in classrooms
Unreliability of the technology
Lack of leadership and support from principals
Lack of institutional support and encouragement
Poor technology infrastructure
Class timetabling difficulties, short lessons

Elliott further proposed the following factors should be considered for the adoption of ICT in schools: school leadership, teacher competency, level of support, teachers of LD and ICT ongoing,

Assisting Students with Learning Disabilities Through Technology, Table 3 Process barriers for ICT adoption. (Source: Elliott 2005)

Process barriers	
Poor teacher attitudes toward technology, lack of teacher confidence	Lack of professional development or inappropriate PD
Conflicting information on the value of ICTs in learning	Lack of time for planning and preparation
Limited teacher skills and competence especially in the face of rapidly changing technology	Lack of involvement in computer room and/or classroom layout/planning
Classroom management difficulties	
Difficulty to adjusting to new pedagogies	

teacher awareness, and teachers' view of ICT (Soderstrom 2009).

In a study by Bates et al. (2007), models of early adoption of ICT innovation in education were considered. In particular, the characteristics of early adopters were reviewed, and these basically related to the following main areas:

- Experienced microcomputer users
- Individuals displaying opinion leadership qualities
- Individuals more likely to investigate new developments

Elliott (2005) further argued that in order for technology to be accepted and incorporated in learning and communication, the following three main areas must be considered:

1. Encouragement of teachers to embrace ICT in their teaching and school culture.
2. Investigation of how ICT can best support and improve the learning outcomes.
3. Analysis of the impact of the digital divide.

In general, Australian teachers felt that they did not have adequate support for effective ICT use and integration of ICT in the curriculum. This view was also supported in research studies by Becta (2005). Moreover, research studies by OECD (2005) and Meiers (2009) provided similar arguments and concerns from the teachers.

Environment for Technological Innovation

National and other studies on the use of technology by Newhouse et al. (2002), Shaddock (2007), Meiers (2009), and White (2005) established that ICT has a positive effect on teaching and learning. In the UK, Becta carried out several research studies to determine the impact and adoption of ICT in schools.

The movement and acceptance by schools of technology is summarized by Ertmer et al. (1999):

Despite the fact the number of the computers in teacher's classrooms has increased dramatically in the last 20 years, researchers and educators alike report that integrating technology into classroom curricular is not easily accomplished. (Ertmer et al. 1999, p. 54)

Undoubtedly, technology has been adopted and integrated successfully in the administration of schools. In Victoria, for example, this was promoted and progressively rolled out through policy initiatives between 2000 and 2006. The aim is to provide a standardized platform for Victorian government schools in order to help them manage their core administrative and finance functions. The software, called Computerised Administrative System Environment in Schools (CASES21), is an integrated school administration and finance system that supports approximately 1600 government schools. It is designed to facilitate schools with data reporting to the Department of Education and Early Childhood Development (DEECD). Although the Auditor General's 2008 Report findings show that the system has improved school administration for a broad range of schools, there are a number of large schools that have reported that the perceived benefits have not yet been fully achieved (Auditor General's Report 2008, CASES21 2008).

A report by Cuttance on school innovation concluded that school classrooms were adapting to the needs of students so that they can develop skills and knowledge to use information, to collaborate, and to communicate effectively with others through ICT (Cuttance 2001). The report further stated that there is no unequivocal evidence about the impact of ICT on the learning outcomes of students although a significant number of studies had indicated that there is potential for ICT to improve the learning outcomes.

In addition, similar to the findings from Becta (2005), the report supports the view that computers in classrooms increase student motivation and increase student control over learning and access to information (Shaddock 2007; Meiers 2009).

The last example to innovations and projects in this section is the Innovation and Best Practice Project (IBPP) from the Cuttance (2001) report. The report included a study on the impact of laptops with 20 schools in the special project (IBPP). For one of the groups where the students had their own laptop, the research evaluation for the innovation program did not produce evidence of their impact to be as strong as the group that used desktop computers. The innovations were based on constructivist learning principles because contemporary learning theorists argued that this was the most appropriate way to facilitate the students learning outcomes and allowed them to control their progress in ICT integrated classrooms (Shaddock 2007, and Cuttance 2001).

The Value of Using ICT in the Education of School Students with Learning Difficulties

Children with Learning Difficulties

The Good Schools Guide (2016) points out that: “Some students who have no obvious physical or mental impairment can have trouble managing tasks necessary for learning, such as concentrating, keeping still, making themselves clear or understanding tasks set in class.” The term “learning difficulties” (LD) is used to refer to this quite large group of children who need extra assistance with schooling that arise from a vast range of cognitive and physical impairments.

Several related terms are “special needs students,” “students at educational risk,” and “students with specific learning disabilities.” While the terms “special needs students” and “students at educational risk” mean essentially the same as “students with learning difficulties,” the term “specific learning disability” refers to a distinct handicapping condition for a small sub-group of students who exhibit severe and unexplained problems. In this entry we will refer only to “students with learning difficulties.”

Learning Difficulties Australia (LDA 2016) notes that in Australia, the term learning

difficulty refers to those students “who experience significant difficulties in learning and making progress in school, but who do not have a documented disability such as an intellectual disability” and that about 20% of students (LDA 2016) have some form of learning difficulty in some aspect of learning. Most schools are able to help these students in some way by setting up special classes, by working with teachers and parents to help them in ways of coping, or by the use of specialists. In other cases special schools offering greater support and a specialized learning environment exist to cater for these students.

Many countries have tackled the dilemma of school membership for students with learning difficulties considering whether these students should be kept in mainstream schools or moved into special schools designed to cater for their needs (Adam et al. 2006; Laabidi et al. 2014). Although many researchers claim that it is best to integrate these students into classes within mainstream schools, numerous “integration” or “remedial” programs in mainstream schools have proved ineffective for the total learning of this group of students. There is strong evidence to support the existence of segregated special schools, and there are around 35 special needs schools in metropolitan Melbourne (Australian Schools Directory 2016). Many previous studies on LD have focused on only one or two specific factors such as IQ, but the literature shows that IQ does not yield valid results or assessments here. The literature also provides examples of where these students in normal classroom settings achieve little success in situations where technology was not regarded as an integral part of the curriculum (Meiers 2009).

The research underpinning this entry was primarily undertaken in two special schools in metropolitan Melbourne, Sunbury and Macedon Ranges Specialist School and Concord School, concentrating on their use of ICT and computers in classrooms. Discussions were also held with two local polytechnics and an industry training organization on the possible further education of these students.

The study reported here was highly motivated due to work with students with learning difficulties over a long spanning teaching career. Special school programs were coordinated such as the school's federal government funding for special schools program (DSP). This program was set up for the allocation of resources for students with special needs in the 1980s. This interest and motivation culminated in the present research study. It led to the close participation and observation of students with special needs in two outer suburban (regional) special schools (Macedon Ranges and Concord) and, in addition, an individual case study to apply some of the early findings and make a comparison. One of these schools provided a basic ICT infrastructure for its staff and students, while the other provided a more enhanced "state-of-the-art" ICT environment that was integrated into the school's curriculum.

These two schools provided two distinct geographical groups of students and were observed over a significant time period. During this time various government departments and agencies were also visited so as to gain an insight into the level of ICT support for students with learning disabilities (or special needs). These included Technical and Further Education (TAFE), the Royal Children's Hospital (RCH), and also some private individual consultants. These consultants worked with a significant group of LD students on a regular basis on language skills and speech pathology at RCH.

In closing this section it should be observed that an investigation on the infrastructure provided a strong link with the Department's IT services. This link enabled the study to determine the level of support that existed for school projects including those that involved ICT with video-conferencing. Furthermore, the Department provided the necessary support for the investigation and analysis of the infrastructure; indeed, this support was essential for setting up the link between the special schools through the Local Area Network (LAN) of the Department.

Methodology

This research was qualitative, framed by actor-network theory, and involved case studies at two special schools in suburban Melbourne over several years by one of the authors who attended and observed specific classes at these schools on a regular basis. Due to the sensitive nature of this area, special approval needed to be obtained from the Victorian Education Department. This allowed a single researcher to enter and observe activities in the school classrooms. The case study data described in this entry was collected mainly between 2003 and 2008 (Adam and Tatnall 2012) and consisted of interviews with the school principal, teachers, and parents (Adam 2011; Adam and Tatnall 2014) on student learning, attitudes to learning, and overall progress. (School pupils could not be formally interviewed under Education Department ethics rules, although informal discussions with some students were held.) As this was exploratory research and the data sample was not large, no claim was made to the generalizability of the findings although it was suspected that further research would confirm them.

Special schools are especially complex socio-technical entities, and research into their infrastructure, organization, and curriculum needs to take account of this complexity. A significant difficulty arises in framing research in a situation like this that involves both technological and human actors ranging from students and teachers to software and broadband connections. When dealing with the related contributions of both human and non-human actors, actor-network theory (Callon 1986) provides a useful framework. Actor-network theory (ANT), or the "sociology of translations," is concerned with studying the mechanics of power as this occurs through the construction and maintenance of networks made up of both human and non-human actors. It attempts to allow for the socio-technical nature of research of this type by giving due and equal treatment to the interactions of both the human and the non-human actors that are involved in each situation and to deny that in regard to technological innovation, purely social

or purely technical actions are possible. ANT reacts against the idea that characteristics of humans and social organizations exist which distinguish actions from the inanimate behavior of technological and natural objects, instead offering a socio-technical approach in which neither social nor technical positions are privileged (Adam and Tatnall 2012).

The actors involved in the adoption of this technology to assist students with special needs were found to include the students, their parents, their teachers, school principals, school ICT specialist teachers, the school council, the Web, microcomputers (Windows and Macintosh), laptops, iPads, software, Education Department policies, learning technology policy, the school environment, classroom environments, learning approaches and paradigms, delivery methods of instruction, engagement methods, thinking processes, technology infrastructure-bandwidth, curriculum, Internet resources, digital libraries and other related mainstream, and special schools (Adam and Tatnall 2010).

The methods employed in this research come from those of case study. Yin (2014) regards a case study as the preferred method for examining questions that ask the how or why of contemporary events or when the relevant behaviors cannot be manipulated. He believes that case studies use many of the same techniques as a history, but add direct observation and systematic interviewing. Case study evidence can come from documents, archival records, interviews, direct observation, participant observation, or physical artifacts. In this research study, key (human) actors – teachers and parents – were identified and interviewed about the use of ICT in the school. Questions to the teachers were broad and asked whether, and if so how, the use of ICT in the school had made a difference to the students' learning outcomes. Parents were asked to identify any changes in their child's attitude to learning and ability to perform educationally. The computers and software (non-human actors) were "interviewed" by examining their operation, instruction manuals, and facilities.

Following the main data collection period, contact was kept with Concord School through ongoing conversations with the principal and attendance at a Concord Conference in 2008. After completion of the initial research project, although access to these special schools was no longer possible (under Education Department ethics rules), follow-up discussions were also held over several years with principals and teachers from nearby and feeder schools to see if anything had changed from their perspective. These discussions suggested that what was observed during the case studies was still continuing, and perhaps even accelerating, after this period.

Case Study: Sunbury and Macedon Ranges Specialist School

Sunbury and Macedon Ranges Specialist School is a purpose-built school for students with learning disabilities. It has around 180 students with 70 teaching and support staff and provides a range of educational programs for students who present with special learning needs including global development delay, autism spectrum disorder, and physical, social, and emotional disabilities and provides an extensive curriculum consisting of Arts, English, Technology, Health and Physical Education, Studies of Society and Environment, Science, and Maths. In addition to delivering the key learning areas as part of the curriculum, the school provides a broad range of programs that are designed to further enhance the independence of its students. The school motto of "Consistency, Credibility and Continuity" is reflected in the curriculum delivered and underpins all that the school's website claims the school represents (Sunbury and Macedon Ranges Specialist School 2016).

At Sunbury, ICT was used predominantly to reinforce language and numeracy skills. An examination of the school's technology policy and curriculum showed that the use of ICT was an integral part of classroom teaching and learning (Adam 2011) but that access was rather limited.

The reported research involved a small-scale project of observations and discussions with the principal and several teachers as well as a small group of students aged around 14. The students were of mixed cognitive and physical disabilities and in general were keen to use computer games (AbilityNet 2013) that reinforced certain skills like language or numeracy and literacy. The researcher chatted with a few students, Ben, Barry, and Teagan, and watched them play the Magic School Bus on Mars. This showed how puzzles were used in this setting to engage students and help them to improve their perception of space, time, age, and personal attributes (Adam 2011). The students investigated were heterogeneous in LD as there were both physical and cognitive disabilities present in the group. At the school there were certain students with severe physical disabilities. Several students needed help with the CTRL-ALT and DEL keys on the keyboard, and a few needed directions as to how to shut down the computer and the order that the various keys had to be used.

Overall though the students were familiar with their environment and were able to relate to and use technology in a comfortable manner. Parents were generally supportive for the initial ICT study and infrastructure. One technical task was setting up the infrastructure for links between different classes at the local level. In working between classes, the students showed a tremendous level of enthusiasm and immediate engagement when they began to communicate via web cams. The students were provided with an opportunity to respond to the researcher's open-ended questions relating to "My technology skills" and "Uses of technology." Figure 8 shows the list of skills and uses of technology from two of the students at the school.

Sunbury and Macedon Ranges provided a gateway into this research and facilitated an investigation of the infrastructure for school ICT. The results were very significant, enabling identification of the level of support both at the local school level and from the Education Department. The school was also instrumental in

Assisting Students with Learning Disabilities Through Technology,
Fig. 8 LD students' skills and uses of technology: early adopters

identifying Concord School, where a significant part of the study was conducted.

Case Study: Concord School

Concord School is a special school located in metropolitan Melbourne that caters for special needs students with mild to moderate intellectual disabilities from Primary (elementary) to Year 12 (senior secondary) levels. The students come from diverse socioeconomic backgrounds and are between 5 and 18 years of age. The vision of this school community encompasses a commitment to achieving excellence in education for students with additional learning needs through a curriculum which integrates learning technologies with best practice in teaching and learning. The values embraced by the school community are “Respect, Personal Best, Happiness, Cooperation, and Honesty.”

Concord has a teaching and educational support staff of 110 with an enrolment of about 400 students. The school’s website (Concord School 2016) proclaims that “Concord School is a government P-12 specialist school for students with additional learning needs. It provides a safe and supportive learning environment where students are challenged to achieve and reach their full potential.” It indicates that Individual Learning Plans are used to specifically tailor the educational pathway of each student to meet their targeted learning needs (Adam 2011). This is done through the use of good resourcing, class sizes of 8–12, and education support staff in each classroom. There is also specialized staff consisting of a school nurse, occupational therapists, speech pathologists, and student well-being coordinators. The school has an excellent IT Resource Centre housing the latest technological equipment for use by its staff and students. Classrooms are equipped with an electronic whiteboard, and each student has access to a notebook computer and iPad. The students at Concord School are encouraged with the school motto: “To be the best that they can be.”

For senior students in the school, the curriculum offers alternative studies such as the Victorian Certificate for Applied Learning (VCAL). ICT was clearly seen as a driving force for students

with special needs. Concord had a One-to-One (121) Information and Communications Technology initiative in its Transition Centre. In simple terms this required the school to invest in a computer (laptop or desktop) for each student, as well as other accompanying software and hardware (including a classroom interactive whiteboard) for VCAL students. The 121 ICT project offered opportunities for students to use technology that would improve their literacy output, access and exposure to technology, as well as increasing engagement (Adam et al. 2006) and provides evidence that scaffolding with a direct teaching approach enhances the learning outcomes of LD students.

In addition, the study further demonstrates that infrastructure is a significant factor in the successful adoption of ICT in these schools. A major part of the reported research was related to VCAL studies, where the students’ daily work was aimed at completing the set tasks. In addition this program provided access to work and further study with the assistance of local organizations and programs from tertiary institutions. In terms of learning outcomes, the students were involved in activities that allowed them to become familiar with current events, national issues, and disasters (Adam 2011). The ICT programs and environment were reflected in the attitude, motivation, and communication skills of the actors.

Overall, observations and discussions at the school found that a strong focus on the use of technology in teaching and the curriculum can lead to stronger engagement by students and teachers. Although in some cases students faced difficulties with motor skills including writing, drawing, spatial perception, and speech, it was observed over a significant time period that these handicaps were often overcome with the use of ICT. For example, folding a blank sheet of paper to make an envelope and then writing their address on the front of the envelope were very difficult for some of the students. However, almost every student was able to use a laptop and a Word Processing program to do this. It was also apparent that some of the students demonstrated ICT skills beyond what was

required in class, and because of this, they tended to show frustration with the teacher in class. The activities appeared to be commensurate with the standard of the students, and the main activities observed included personal development, office skills, and ICT studies (Adam 2011).

The school principal fully supported the research and felt that the school could only benefit from an independent examination of the way ICT was used and how it could be further used to support the 121 project. This was a key actor who displayed very strong leadership, and this was recognized and respected by the school staff, students, and other stakeholders. He was an early adopter of the technology and held the belief that students with LD could be assisted by the use of technology or ICT in the classroom. This actor saw the strength of the school in the strong bond that it had with its students. Everyone in this school community – teachers, parents, assistants, students, and ancillary staff – all had access to the principal who was active and involved in the affairs of the school and very supportive of ICT projects implemented. This was a very enthusiastic actor about innovation with technology and organized work on the infrastructure to get the classrooms ready. His interview comments included the following (Adam 2011):

- “I want to see the students to be active participants in their own learning that leads to specialization in technology.”
- “This empowers students (disabled or not) to control and self-manage their own learning at school and at home and hence become lifelong learners with access to technology and skills.”
- “Technology provides skills so that they can be seen as normal workers and have gained an understanding to take on the role beyond school.”
- “The focus is on collaborative learning with students becoming social and collaborative learners.”

A number of teachers were observed and interviewed on a regular basis, and all

demonstrated full support for the school leadership and vision in regard to ICT. They were all very strong users of ICT, having their own laptop, used email, and also accessing the school’s internal resources through a shared medium (SharePoint). They worked well with the students and implemented school policy, agreeing that ICT was an enabler for the students and that it would improve their learning outcomes, particularly since it was integrated into the curriculum. They showed adequate technical skills and willingness to adopt new technologies. The following comments displayed their belief in ICT:

- “This is an exciting step for students, teachers, and classrooms as it is social and collaborative technology – it is never boring.”
- “Yes and they are growing in an environment where the world is at their fingertips.”
- “It is a whole new classroom that is not contained to that physical building of the school.”
- “It’s not just about playing with a new toy – it’s exciting because it connects you with others.”

Parents of students from several classes were asked to respond to a questionnaire, and the response rate was very high and showed a positive attitude for the use of ICT in the classroom. Several parents indicated an awareness of the use of ICT in the curriculum by the school, and their responses showed that they felt there were still gaps in how technology could assist their child in both school and life. However, they indicated that they had identified a positive gain from ICT and acceptance of the school’s work and curriculum. Parent responses included (Adam 2011):

- “Provides confidence, very useful information, spelling, solving problems, skills for the job, and skills for the home.”
- “Ability to use laptops and programs not at home.”
- “Gain independence in writing and money skills.”
- “Have good understanding of various computer programs, source information, look up

bus tables, concert tickets, movies, starting times, etc. independently.”

- “My daughter’s limitations reduce the degree to which she can use ICT, great learning tools as she is a very visual child, and she likes to be alone often.”

Concord School, Transition Centre

The Transition Centre caters for approximately 60 to 70 students from Years 10, 11, and 12 with the aim of facilitating their transition from school to further education or to work, through learning programs that offered an applied learning curriculum. This could be followed up through courses at a local training organization. The practical and pragmatic approach adopted by Concord was that its Transition Students are provided with a curriculum with a strong focus on ICT. In Year 10, students complete the pre-transition learning program designed to prepare them for their post-compulsory schooling. In Years 11 and 12, students complete either their VCAL or a Special Needs Learning Framework program designed by the school. This ensures that learning continues during and after the transition process and is recognized for employment and educational purposes. It also provides a safety net for school leavers.

The practical and pragmatic approach adopted by Concord is that its Transition Students are provided with a curriculum with a strong focus on ICT. And this subsequently can be seen as a vehicle that allows the students to build lifelong skills. From the USA, the “Individuals with Disabilities Education Improvement Act” mandates equity, accountability, and excellence in education for children with disabilities and provides recommendations in regard to the assessment of standards of LD students in the preparation and continuity beyond college. Concord’s Transition Centre echoes these ideas. ICT is embedded in the curriculum and the beliefs of staff and school community at Concord. It is a strong vehicle and enabler for good pedagogy as it reinforced the communication skills and engagement and is a clear indicator and facilitator for school to work transition (Adam 2011).

This study provided strong evidence that ICT can equip LD students with adequate skills

which allow them to continue with further study through pathways to higher education at a local polytechnic or university. This subsequently can be seen as a vehicle that allows the students to build lifelong skills. The research also showed that LD students can increase their job opportunities as the ICT skills they learn can minimize the impact of their disability or learning difficulty and thus enable them to attain a normal work environment.

At an academic conference in 2007, the ICT coordinator described how Concord School had introduced and trialed the use of social software and networked learning activities and practices. He described the use of relevant software at the time such as Lumil, WordPress MU, ccHost, Urdit, Gregarius, Scuttle, and Firefox by the students at all levels in the school. Table 4 gives a summary of the activities undertaken and what they achieved. Understandably, these have been superseded by more recent programs and tools, but the presence of these strongly demonstrates the significance of this actor.

An Actor-Network Analysis of the Use of ICT for Students with LD in These Schools

Any analysis using ANT deals not so much with the actors themselves as with the interactions between actors and their networks, so ICT is only important here in its interactions with the LD students. Both schools only had significant ICT programs and provided good ICT facilities and student encouragement due to the interactions of their principals with teachers, parents, and the Education Department. The classroom computers are only able to interact with students due to their prior interactions with the school ICT coordinators to prepare workstations, software, and Internet connections. The most important interaction here though is between the students and ICT facilities. We will discuss the data, primarily from Concord School as this was most significant, in accordance with ANT innovation concepts, namely, problematization, interessement, enrolment, and mobilization of actors (Callon 1986) similar to Shaddock (2007).

The leadership of key actors, including the principal, ICT coordinator, and several leading

team teachers who worked in the 121 ICT project, all problematized (Callon 1986) the vision of integrating ICT in the curriculum. The most important actors and their interactions were:

- Ten students of mixed cognitive and physical disabilities at Concord were observed working and interacting with teachers and assistants from the senior class in the 121 pilot project. Their main interactions were with their teacher and the school computers, and they were all keen to use computer games. These acted to reinforced skills like language, numeracy, and literacy. They were also able to exchange email with the principal.
- Parents as actors had their own voice and networks and problematized their own way via the school council and supported funding.
- The principal is very much a leadership actor, gatekeeper, strong voice, and power in the school council. He insisted protocols were followed and held a very strong view on the technology, users, and role of technology on learning.
- The ICT coordinator was another leading actor who was recognized for his skills and knowledge. He was assigned the task to enroll other actors and extend the 121 ICT pilot to the rest of the school. He was an innovator who introduced modern technologies and was

very highly regarded by other actors. He problematized ICT curriculum by applying his ICT skills. He also possessed previous experience from working with specific Education Department projects to train others.

- Leading teacher (1) was a key instigator for the 121 project in 2005 and a willing user of ICT in classrooms. This actor problematized the 121 ICT project and the necessary infrastructure for its delivery, possessed high communication skills, and was very capable in mobilizing other actors.
- Leading teacher (2) was highly trained in special needs work and an engaged ICT user. This actor problematized curriculum studies by integrating ICT in general VCAL studies.
- Computers and other technical objects (in ANT, known as immutable mobiles) and their interactions with students were highly significant. For instance, it was amazing to notice the students' reaction to the tablet PC when they saw it for the first time.

The interactions between the students and computers indicated their considerable interest in ICT and showed that their teachers were able to help them in catching up with schoolwork, looking up words in the dictionary, preparing oral presentations, working on the computer, working out things together, and similar activities. They were clear and accurate about who managed the school and the class they belonged to and clearly identified with their home group teacher. In some classes, they were given responsibility to check the attendance roll and organize orders for the store and lunches. They also collected and distributed laptops and trolleys between classrooms in an orderly manner and appeared happy to go from one class to the next and participate in the activities on hand.

The school learning model developed and changed in response to need and the availability and type of resources. It was proactive, and its focus was on addressing the current needs of students, parents, and teachers. For example, inclusion of social networking concepts like

blogs was introduced in 2007. This enhanced the way ICT was used in the classroom with students engaging and producing work of higher standard and displaying stronger skills. All this curriculum development was done within the frame of Education Department policy.

Conclusion

The research showed that use of ICT enhances LD students' independence and equips them with adequate skills which should allow them to continue with further study through various pathways and to move into a normal work environment. It also demonstrated the importance that key actors, such as the Concord school principal, have in facilitating the adoption and use of ICT with these students. It was observed that in certain activities that required physical or motor skills, some students were able to overcome these with the use of ICT.

Although Concord did use some performance indicators internally and externally through the number of students completing VCAL, in this entry, it has not been argued that test results and better educational outcomes in the commonly used sense of the term were necessarily improved. It has been argued, however, that ICT can be seen to be an enabler for good pedagogy with these students.

The research found that the most effective manner for teachers to implement programs using computer-based technology is to integrate the technology into the curriculum. In doing so, the special needs students gain lifelong skills and enhance their self-esteem and communication skills. ICT is shown to be an enabler for good pedagogy that can also set a pathway for the transition from school to work or further study for these LD students. It does not change the nature of a subject but has the capacity to integrate and consolidate several areas from the field of study or curriculum. This study found that ICT was applied to teach image refinements,

certificate designs, or artifacts in office skills at Concord.

The research data from the case studies demonstrate the power of both human and non-human aspects of the socio-technical network that staff and students construct around LD and the benefit of using ICT in their education. The study provides evidence that for LD students, a significant attainment in skills and academic knowledge is facilitated by the adoption of ICT. This data showed that a strong focus on the use of technology in teaching and the curriculum can lead to stronger engagement by students and teachers. The study strongly supports that ICT increases the motivation, independence, self-esteem, and communication skills of LD students and aids in facilitating transition to work. At least in this respect, producing a different result to that reported in the OECD study, made this research study very worthwhile. The results support the view that ICT has the power to interest, enthuse and inspire these students. This result is illustrated by the comment of one student who proudly said: "We were the first to use a laptop and a smart whiteboard in the school."

²Department of Education, University of Calcutta, Calcutta, India

Introduction

Recently the World Bank reported that out of the 1 billion population (15% of world's population) experiencing some form of disability such as one-fifth of the estimated global total, or between 110 and 190 million people experience significant disability (WHO 2018). Technology plays a vital role for Inclusion as it increases the participation of individual and community at large in all walks of life. Various revolutionary

innovations such as artificial limbs, robotic assistance for feeding, Speech Generating Device (SGD), etc. enables individuals with disabilities more functional capacities.

In general, definition of assistive technology comes from the Assistive Technology Act of 1998, which was amended in 2004. The amendment defined assistive technology as “any item, a piece of equipment or product system whether acquired commercially off the shelf, modified, or customized that is used to increase, maintain or improve functional capabilities of individuals with disabilities” (Cook and Polgar 2014, p. 2). But there is also myth regarding thinking aspect of assistive technology, namely, “technology panacea myth,” that means a psychological state when individuals with disabilities and other related person think that technology itself enables an individual with disability function as without disability (Quist and Lloyd 1997). However, this may not be rightly defined and may actually be the outcome of lack of knowledge regarding the philosophical view of technology and fundamental design principle.

Therefore, this chapter mainly focuses on two different sections: *firstly*, the chapter discusses the philosophy of technology and shows how in the context of philosophical orientation, theoretical and conceptual frameworks of assistive technology are being developed. *Secondly*, it focuses on universal designing aspects of assistive technology. The chapter intends to redefine assistive technology based on these two aspects in the context of inclusion and tries to answer some questions related to mainstream technological design. In a major aspect, this chapter seeks to explore some of the basic questions related to technological design and its use in the context of assisting the people with disabilities in the context of inclusion such as – how an assistive can be defined in the context of inclusion? Besides, this chapter will also explore an overview of how the knowledge of philosophy for technological design is crucial to designing an assistive technology device for inclusion.

Philosophy of Technology for Inclusive Accessible Design of Augmentative and Alternative Communication (AAC)/ Assistive Technology (AT)

This is a relatively new concept in terms of Augmentative and Alternative Communication (AAC)/Assistive Technology (A.T). This section will reflect the philosophical overview of technology. This is important because technology itself is not a miracle which can bring change and enable people with disability function like without a disability. The success of any AT always is based on design and functions of the specific device with respect to the context be it environmental, cultural, psychological, etc. Therefore, in order to understand technology properly in the real sense, there is poignant need of understanding the underlying philosophy. Any designer, user, or family member of user and practitioner needs to know more about the nature of technology through the lenses of philosophical inquiry to understand the essential approaches needed to use AT in inclusive settings.

This section is organized through different domains of the philosophy of technology which is mutually interrelated in the context of AT design and inclusive accessible viewpoint. Next part provides an overview of the philosophy of technology as a contribution on a theoretical and conceptual basis of AT and at the end draws some conclusion from the point of view of design and application of AT.

Researchers are very much interested in the philosophy of science rather than the philosophy of technology. However, quite recently philosophy of technology is also getting an increasing amount of interest and attention among the researchers. The most comprehensive viewpoint of philosophy has been given by Carl Mitcham (1994) in his book “Thinking Through technology” where he conceptualizes it from three aspects/angles: “technology as artifact,” “technology as knowledge domain,” and “technology as social values” (Vries 2010b).

Technology as Artifacts

Mitcham believed that every technology is an outcome of “Artifact.” But generally, people are not aware of the artefact and think that everything can be technology. In any circumstance everywhere is an artifact, but people associate them with technology. In the field of technology for people with disability, in many ways people just assemble amount of artifact to diminish the specific obstacles for people with disability and called it as a technology. Therefore, artifact is one of the direct ways of connection with technology. Another way we can define “artifact” is as a functional nature of “natural object.” So here one needs to clarify the complimentary concept of “artifact” and also explain why artifact is different from “natural object.” According to Meijers (2000), artifacts incorporate two different natures with specific properties:

- (a) **Physical/structural properties:** Physical or structural properties of artifact refers to the element of an object. For example, think about ones’ smartphone, one can describe the phone based on its elements (such as plastic), size (5 in.), color (black), weight (5 gm.), shape (square), etc. But one who is not familiar with a phone or its function, may think it as an object for dressing hair or even digging soil.
- (b) **Functional properties:** Alternatively, “smartphone” can be described based on its functional aspect such as one can talk through it from a distance or the Internet can be surfed by it etc. Now, who is not familiar with this can imagine some of the basic images such as how the object looks like, or its shape, and so on and so forth.

Furthermore, these two descriptions of an artifact are incomplete without a combination of both. Such as only physical/structural properties cannot give the whole image of an object or vice versa. So now if one tries to know about “natural object,”

there is only physical/structural properties and no functional properties. It is the human who defines the functional properties of an object and makes it an artefact. This concept will be further analyzed by providing examples from the assistive technology point of view. For instance, suppose when one thinks about a “rubber” while someone uses it as a pencil grip for the student with Tourette syndrome (i.e., who has difficulty controlling motor pattern for writing). In that situation, “rubber” is a natural object and that is the human who ascribes “function” aspect to it (viz. use it as a gripper). In that way, natural object (here rubber) can have many “function” such as it can be used for hair binding or pencil gripper and many more ways. However, in that situation, natural objects will be treated as an artifact. Therefore, size, weight, or color doesn’t depend on the idea of rubber, rather “function” does (Vries 2010b).

Moreover, from the functional view of artifact, Hendrik van Riessen (1938) discussed about “aspects of reality.” “Aspects of reality” means functions of artifact from different aspect. He also elaborated that every artifact may have 15 aspects of reality. Some of them are as follows:

- **Spatial aspect of reality:** Every artifact occupies a certain amount of space. So, designer of any artifact must take this into account.
- **Economic aspect of reality:** Every artifact has its own value (from the economic aspect – the price tag). This value depends on what “function” someone ascribes for it.
- **Social, judicial, aesthetical, ethical, and belief aspect of reality:** This aspect means belief or distrust in any technology.

Another viewpoint that may be important to discuss here is that every artifact will have subjective as well as objective functions. Such as in the physical interaction point of view, pencil gripper, as an assistive artifact, can function as both subject and also object. Subjective in the sense, pencil gripper can itself diminish the

problem of writing for Tourette syndrome and objective in a view that human beings can change or modify pencil grip for his/her own convenience. Therefore, designer of any assistive technology or better to say who ascribes function to any artifact must reflect its various aspects such as passive, active, or both in order to function it as desired.

Now another important aspect necessary to explore here in order to get a sound view about designing any AT are the following:

- **Proper function:** Proper function refers to a specific function which designer (or any human) had in mind when he/she ascribed functions on it. Such as pencil gripper can be used in many ways but the designer who designed it, ascribed function of writing as a pencil.
- **Accidental Function:** But the element or physical property of pencil gripper can be used in several ways such as someone can use it to resist the pen falling down from the table. That is the accidental function of an artifact. It is very common that the accidental function may work properly because physical elements of specific artifact are fit to do that.
- **Improper function:** Suppose someone wants to use pencil gripper for breaking the glass but it doesn't work because physical properties don't allow doing this. Therefore, it may be considered as improper function.

From the functional aspect, Van Riessen also discussed two distinct functions of an artifact such as foundational function and qualifying function.

- **Foundational function:** The foundational function of any artifact refers to the origin of an object. Such as a stone was formed by many physical processes that is why one can say that a stone has its foundational function in the physical aspect (Vries 2010a).
- **Qualifying function:** Qualifying function refers to ultimate contribution of any object to the meaning of reality. For instance, for a

pacemaker the qualifying function of reality is that to produce the correct electric pulse. This can be characterized as technical function. Varies (2010b) described that the qualifying function of a train is in the social aspect such as carrying people together. But this "social aspect" can only take place when train fulfills the technical function that is the "spatial aspect," i.e., going from Place A to B.

In the view of the previous example of pencil gripper as an assistive technology, the element of rubber gripper or wood for pencil has had its own foundational function separately.

Apart from all foundational or operational functions, there is another crucial aspect of an artefact which corresponds to "operation" or "functioning in a specific action." It means that application of multidisciplinary way to derive knowledge about physical and functional properties to predict how a specific artifact behaves in a certain action. In that situation, effective design of an artifact should reflect the desired function. Additionally, an artifact can be consisted of many parts; in that case, artifact denotes a "system." A system is a combination of many parts of an artifact working together.

Here an overall discussion about the philosophy of technology as artifact provides background knowledge about how philosophical reflection of technology can influence the design of any assistive technology. This knowledge is pertinent to design an assistive technology for an inclusive setup. Many times it has been observed that poorly designed assistive technology stigmatize student with peers without disability (Hayhoe 2014). Only awareness or academic setting through assistive technology doesn't contribute to the process of inclusion of people with disability (Krüger and Berberian 2014), there is necessity of ascribing function to it. Many assistive technologies mainly focuses on hardware or software function rather aesthetic aspect of reality, the cultural aspect of reality, and social aspect of reality (as discussed in the previous section) in context of mainstream settings. The subsequent section

of the chapter is going to discuss another important aspect, namely, design principle of AT for inclusion.

Design Principle of AT for Inclusion

The concept of “inclusiveness” refers to equitable or equal opportunity or participation of the “people with disability” by providing them a platform where they can exhibit their different abilities with their neuro-typical peer (Ahmad 2015). Though various AT has been developed to assist the “differently abled” community, there are always emerging needs and challenges to tailor-made or personalize the design of AT device to increase more participation in an inclusive setup (Carmien 2016).

This section focuses on the designing principle provided by Quist and Lloyd (1997). Quist and Lloyd (1997) portrayed six standards of AT which are needed to be taken into consideration when designing any assistive devices. The six standards are as follows: (a) Principle of parsimony (b) Principle of minimal effort (c) Principle of minimal energy (d) Principle of minimal interference (e) Principle of best fit (f) Principle of practicality and use, and (g) Principle of evidence-based practice.

Principle of Parsimony

Everything should be made as simple as possible, but not simpler – Albert Einstein (Reader’s Digest in July 1977)

“Principle of Parsimony” refers to that a design of AT should be simplest to increase effectiveness and efficiency (Quist and Lloyd 1997). Complex design can be a very effective solution but that can also create barriers for users, especially those who have struggled with various physical and mental challenges. Therefore, when designing or selecting any technological devices, the designer and end-user should be concerned about unnecessary complexity and implement easy to understand approaches (Jones 2002). Generally, in daily life activities, people are intended to use various complex

solutions which can easily be substituted with the simplest solution (viz. inexpensive, reliable, and easy to transport) (Lee and Johnson 2017). For example, those who have “Tourette syndrome” or difficulty in a motor pattern for learning, one of the major struggles is “writing.” Therefore, he or she can easily buy “voice recognition software” for writing or can use low technology such as “pencil grips.” But if both this technology helps in writing then choosing simple one is the less expensive, easy to transport, and less time consuming (Quist and Lloyd 1997). By diminishing complexities, active participation may be enhanced and hence inclusion can be improved.

Principle of Minimal Learning

Don’t Make Me Think – Steve Krug (2006)

Another hindrance for active participation or inclusion of people with disability is the use of poor design while developing AT devices that require additional thinking or mental effort to use or understand the function (Malcolm and Roll 2016). The principle of minimal learning refers to less cognitive load aspects when using devices. For example, in 9th grade, the teacher gifted a new design pen to all the students in the class. There were various instructions given by the pen company regarding how to open the pen and write. However, after sometime classroom was getting too much noisy and lots of queries were poured in to the teacher, lots of broken pen in hand for the inappropriate opening and lots of frustrated faces. So, why this situation happened? The answer is as the designer of the pen company did not maintain the principle of minimal learning. Therefore, to use or understand the function of pen, the users required more mental effort which increased the cognitive load and decreased the motivation to use it (Malcolm and Roll 2017).

Therefore, in the context of designing AT devices, designer should be concerned about less instruction on how to use it. King (1999) pointed out it as “operational knowledge,” knowledge regarding “how to use” or “operate” any devices. Quist and Lloyd (1997) noted that if any device

required more “operational knowledge,” it likely reduces the use of the device over and over time by the user.

Principle of Minimal Energy

Minimum effort means maximum comfort – Cited by Aarts (2006)

Minimal energy refers to the least necessary mental and physical effort for any task performance. Research has shown that task which required huge energy for task performance, there will be less motivation about specific task completion (McDonnell et al. 2003). This can be worst in context of people with disability. Quist and Lloyd (1997) found that AT user most likely to avoid any task performance if there is need of too much energy. Therefore, designer of AT must take into consideration this principle to increase performance for long period of time. From the designing perspective, the Center for Universal Design at North Carolina State University (1997) provides some guidelines to minimize effort in task performance. Some of those are natural body position of user which should be maintained in any design. Those are the following:

- Reasonable operating forces should be executed.
- Repetitive action should be minimized.
- Sustained physical effort should be minimized.

In the context of AT device, this principle can be utilized for motivation or to execute a behavior. Any user can be withdrawn from any task related cognitive load or mental effort and physical effort that is more than the motivation of user.

Principle of Minimal Interference

Stop brothing me! – Cited by Quist and Lloyd (1997)

This principle emphasizes that any design of AT should create a distraction-free environment. This principle is important to take into consideration as if any AT design has more complex or multiple features then attention of any user will be engaged in operating the device rather the task performance (Shaffer 2017). In such situation extrinsic cognitive load will be increased; therefore, the user may

experience low motivation from the required task such as learning activities or communication.

Principle of Best Fit

Is it me? – Cited by Quist and Lloyd (1997)

This principle emphasizes on individualized design of any AT. A designer should be aware of the target group or individual to design a “best fit” device based on personality or need of individual or community to the maximum extent possible. Quist and Lloyd (1997) stated that design which is compatible with user need and the personality of a user AT becomes more effective for people with disabilities. Ergonomic or understanding the human factor is major study area in the field of any technological design. King (1999) claimed that 75% success of any AT device is related to the human factor.

Principle of Practicality and Use

Never forget why you started – Cited by Quist and Lloyd (1997)

This principle supports feasibility and practicality of any AT device. Design of any device needs to be consistent with the availability of resources. Therefore, this principle emphasizes to apply previously mentioned all the principle from the practical ground. For instance, mental effort, cognitive aspect, physical or environmental aspect need to be taken into consideration based on the availability of resources. In a simple way, this principle encourages to develop a solution which can actually use in real-world context. Therefore, designer should keep in mind economic, social, mobility, psychological aspect, etc., while designing devices (Hayhoe and Simon 2014; Yu and Liang 2013).

Principle of Evidence-Based Practice

Stand on the shoulders of giants – Isaac Newton on Letter to Robert Hooke in the year of 1676

Another important principle for designing an AT device is Evidence-based practice (EBP) (Thistle and Wilkinson 2015). Schlosser (2003) stated three aspects for EBP such as (a) use of best and most current research as a reference for design (b) focus multidisciplinary team or expert approach (c) need to take all the stakeholder perspectives in

consideration for best services. EBP is the most critical aspect of AT development for any technological design for the following ground:

- Research-based pieces of evidence can help educator or designer towards effective implementation of AT for assessment and intervention (Schlosser and Raghavendra 2004).
- EBP increase accountability through a literature survey and help to find out effective strategies and interventions for present and future design of AT (Logemann 2000).
- EBP helps to provide insight regarding equal weight to unique client (Schlosser and Sigafoos 2009).

In this particular discussion, it has been observed that for designing effective AT devices the designer should know the fundamental aspect of technology from the philosophical viewpoint. Besides, a designer needs to know design principles to develop new forms of mainstream technology through innovation. In fact, we are living in an innovation era, where every nanosecond we are witnessing innovating some or the other new technologies. This is also true in the field of AT devices. This is privilege for us, however may not be every time. Because this may create a problematic situation in the context of inclusion, therefore, we need a serious (Re) philosophical evaluation of any AT so that it can contribute most effectively and purposefully to the mainstream technology or inclusion. Based on the reflection above, the next section is going to conclude assistive technology in the context of inclusion and intends to answer some relevant philosophical question in the context of design and functions of assistive technology.

Conclusion

Now coming to the end of the whole discussion, after providing general knowledge about the philosophy of technology in the context of AT including knowledge about design principle for designing effective AT device, the final section intends to link together and try to redefine technology as an assistive approach in the context of education. Here one tries to answer two specific

mutually exclusive questions; (a) What is meant by assistive technology in the context of inclusion? (b) How designers can use the knowledge of philosophical aspect for designing such inclusive technologies?

A straightforward approach to answering the first question is no people with disability should separate from his or her nondisabled peers by using any AT device. As discussed earlier that poorly designed assistive technology stigmatize student with nondisabled peers (Hayhoe 2014). Therefore, technology needs to be inclusive. Hayhoe (2014) also discussed inclusive technology is such technology that encourages social inclusion in the context of communication and interaction for the people with disability. The philosophy behind the inclusive approaches in AT technology and design is that it is our fundamental right that everyone should have social and cultural equality in the context of education and communication.

Consequently, the second question can be answered from several points of view. One of major important aspect needed to be taken in to consideration is (re)shape and (re)define the terminology “assistive technology” (Hayhoe 2014). This can only be done when designers of assistive technology shift their focus from the design of AT for people with disability to inclusive designs by addressing the social and cultural inclusion issues in their design. Additionally, need to design any device, not customer-led rather the intention to assist for whom the technology is created. To make a drastic shift in the context of assistive technology for inclusion, there is poignant need to provide encouragement and training to people with disability so that they are skilled to make their own devices (Simon 2014). Furthermore, it needs to be emphasized that people with the disability still have human capital that is valuable to their society.

Assistive Technology and the Gifted Learner

Tamra Stambaugh and Jacob Pierce
Vanderbilt University, Nashville, TN, USA

Synonyms

Acceleration; Distance learning; Gifted; Online learning; Web-based learning

Assistive technology is generally defined as piece of hardware, software, or other product that is used to help individuals perform tasks that might otherwise not be possible – especially those with cognitive and physical impairments (ATiA 2018). In the USA, a federal definition for assistive technology exists and policies and regulations provide protections and exclusive rights for those with disabilities needing certain technologies. Though not legally binding, some individuals have broadened the definition to include anyone who needs special accommodations in order to access appropriate learning, including gifted learners (Ellsworth 2018). Some states and higher education institutions in the USA consider gifted students within the special education umbrella and require that districts write Individualized Educational Plans for them. While the same federal legal rights do not apply, the individualized plan within a state allows gifted students to access learning tailored to their needs. Still, it may seem counterintuitive to consider gifted learners as a population that requires or benefits from assistive technologies. When one does think of assistive technology and gifted together, generally it is because a student is twice exceptional, meaning they are identified as gifted and also have a cognitive or physical impairment.

It may be argued, however, that gifted children differ from the general population in ways that require special accommodations and services not typically provided in the general classroom in order to continue learning at an expected pace and as to not impede their rate of learning. Gifted learners differ from their same-aged peers in a variety of ways. They are more likely to make complex connections within and across disciplines, learn (and retain) information more quickly, and understand abstract and theoretical ideas at deeper levels. They require accelerated instruction with appropriate levels of challenge and pacing in order to excel (Thomson 2010). Without the necessary accommodations, gifted students are less likely to show learning gains that are commensurate with their abilities and to achieve at expected levels (NAGC 2010). Consider, for example, a 6-year-old gifted student who already understands plot development, characterization, and how

language impacts a story but has not yet developed fine motor skills to write down all of her ideas because her physical development is not synchronized with her cognitive development. She may benefit from assistive technology to help her convey her ideas and continue learning and practice new concepts at a pace necessary for her until her fine motor skills develop enough to write the stories independently. As such, the use of assistive technology supports her cognitive development and eliminates the fine motor development concern that could have impeded her learning.

Evidence suggests that the use of technology in gifted classrooms offers benefits to both students and teachers (Housand and Housand 2012) although there are limited empirical studies on the topic. Strategies such as acceleration, interaction with like-ability peers, in-depth study with authentic learning experiences, and access to opportunities, mentors, or more knowledgeable others are effective ways to increase academic achievement and develop expertise (Rogers 2007; Subotnik et al. 2011). Technology may be used as a tool to implement such strategies to help gifted students perform tasks that might not otherwise be possible making it, in the broadest definition, assistive. In particular, the use of hardware, web-based approaches, software, online collaboration and discussion forums, and online coursework are the most studied interventions that have positive results for accommodating gifted student learning needs.

Hardware

The use of technology to develop content expertise, coupled with becoming more proficient in a variety of technology platforms, programs, and hardware can enhance gifted student learning and critical thinking. The use of graphing calculators, simulation tools, and digital drawing tools at earlier ages serves as a way to accelerate learning, allowing gifted students to become proficient in using advanced tools in a discipline at earlier ages consequently increasing conceptual understanding and spatial skills (Duda et al. 2010; Gadanidis et al. 2011).

Web-Based Approaches

Liu (2004) found that using specific hyperlinks (i.e., links to videos and online lectures and other advanced resources) increased gifted students' higher-level thinking skills and attitudes toward learning. The use of specific hyperlinks for independent learning also allows gifted students to adjust the pacing of their own learning and learn at a pace and depth more commensurate with their abilities, showing higher self-regulation skills (Greene et al. 2008).

Software

Software programs support individualized learning and advanced pacing so that gifted students can pursue areas of interest in depth (Sanderson and Greenberger 2011). In one study, e-publishing software allowed gifted students the opportunity to develop and showcase their talents at a pace appropriate for them and consequently they showed greater gains than those not identified as gifted (Gentry 2008). In another study, the deliberate use of game-based software allowed students to increase their problem-solving approaches and strategy development (Steiner 2006).

Discussion-Based Forums

Online platforms and discussion boards as well as collaborative games and software programs allow gifted students opportunities to develop social connections and interact with other like-ability peers. Students can engage with other like-ability peers to promote social-emotional health, share unique perspectives, and connect with others who have similar interests, regardless of age. Shin et al. (2013) found that the use of a software program that incorporated collaboration through sharing ideas about content and story designs increased the reported levels of friendships in

gifted students. Students participating in online or virtual forums may also find a sense of belonging not otherwise enjoyed or accessed in their schools (Cross 2004). Similarly, when educators used online discussion boards, students were more likely to collaborate and communicate with each other, thus developing more advanced thinking skills (Gadanidis et al. 2011). In another study, students who participated in online learning courses reported that one of the positive aspects was the socialization. Further, gifted students reported being more open-minded to different perspectives (Blair 2010) although students still wanted face-to-face or voice interaction with instructors (Olszewski-Kubilius and Lee 2004; Gadanidis et al. 2011); they also preferred online resources with hard copy textbooks as opposed to strictly online work (Gentry et al. 2007).

Online Coursework

The use of online coursework allows educators to individualize and tailor learning to each learner's unique strengths and needs in ways that are not typically provided in the general classroom. Teachers of gifted students might lack the qualifications to teach courses in the subjects their gifted students are interested and proficient in. Moreover, schools may not offer the number or types of advanced courses necessary to support the unique needs of gifted students at a pace or depth necessary for them to continue learning. With the help of computer-aided instruction and online courses, teachers can provide students with the resources needed to continue to learn and develop expertise. Specially designed online courses for gifted students led by content experts as well as adaptive software programs that progressively increase in difficulty provide accelerated opportunities that may not otherwise be afforded. Access to websites such as museums, ask-an-expert forums, and virtual tours of historical places and related websites can be a powerful tool for finding answers to many student

questions. Free courses and lectures such as MOOCs, Ted ED, or Khan Academy allow access to accelerated content calibrated at a level commensurate with gifted students' unique abilities. However, teachers must be careful when selecting online forums for gifted students and ensure that the courses are tailored for gifted learners and appropriate for student use. When online courses are designed specifically for gifted students, they report greater interest in a learning (Wallace 2009), show advanced problem-solving skills, acquire more in-depth content, and score higher on Advanced Placement exams (Olszewski-Kubilius and Lee 2004). Gifted students also reported that the online courses served as a positive way to actively pursue areas of interest in deeper ways, participate in courses not typically offered at their school, to learn at a pace commensurate with their abilities (Olszewski-Kubilius and Lee 2004), and to enjoy more personalized instruction not typically found in face-to-face settings (Thomson 2010; Wallace 2009).

A few cautions must be noted when examining technology and gifted students – especially assistive technology. First, the literature on this topic is extremely limited. In a review of the literature, Periathiruvadi and Rinn (2012) found 24 empirical studies focused on technology and giftedness although 157 descriptive or conceptual articles were found. Many believe that technology can be used to help gifted students access and perform tasks not otherwise available, but there are a few clear empirical studies on the effects. Information on assistive technologies for gifted students who are twice exceptional (i.e., have cognitive or physical disabilities and are labeled as gifted) is almost nonexistent of the few that were available. One article makes recommendations for particular apps that build upon twice-exceptional students' strengths (Stewart 2009) while another highlight ways to use translation devices for gifted students, particularly those who are deaf or blind and from rural areas (Belcastro 2004) arguing that geographic limitations complicate access and technology can assist in equalizing this access for

those in remote populations who are also in need of assistive services due to a physical impairment.

Second, teachers may have an inaccurate understanding of differentiated instruction. It is not enough to apply technology with gifted students as a general instructional strategy. The use of technology alone does not make instruction differentiated. Technology, when used as a differentiation tool, is carefully selected and deliberately applied to help students accomplish or access opportunities not otherwise available. Merely giving gifted students access to technology is not adequate. Differentiation with technology for gifted learners is individualized and targeted to their unique learning needs and strengths.

Finally, professional development and training for teachers and students is required. Students need to know how to effectively and safely use and participate in technology (Siegle 2003; Siegle 2007) and carefully select appropriate sources (Housand and Housand 2012). Not only is it important for students to know how to navigate the world that technology opens for them but teachers also need to be trained to use technology in their classrooms; technology cannot be used effectively if teachers do not know how operate or integrate it into classrooms and lesson plans (Periathiruvadi and Rinn 2012). Students need to be trained to effectively conduct online research and use the tools at their disposal while teachers need to be trained so that technology can be seamlessly integrated into classroom settings. Competing priorities, high stakes testing, little to no planning time, wide ranges of abilities in one classroom, lack of access to appropriate resources, and lack of pedagogical and content expertise can inhibit a teacher's ability to differentiate instruction for gifted learners in the general classroom (VanTassel-Baska and Stambaugh 2006). Technology's benefit cannot be realized if students and teachers are unable to use it properly or current systems and policies are not in place to necessitate use. Moreover, not only do teachers need to realize how to use technology and keep up with the

fast-paced and ever-changing developments in technology but they also need to know how to apply it effectively as a differentiation tool (Shaunessy 2007; Zimlich 2015). Teacher attitudes, access to appropriate technology, student responses to new approaches, and funding approaches all impact the effective use of technology in the classroom for gifted learners.

In summary, the research on assistive technology and the gifted learner is nonexistent. Accepted definitions of assistive technology are narrowly defined and do not include gifted learners as a special population that requires assistive technology. This may be due in part to federal guidelines for funding as well as philosophical beliefs. Regardless of the definitions, it is well documented that gifted students have learning needs that necessitate attention and accommodation (NAGC 2010) in order to develop at a pace commensurate with their abilities. Moreover, gifted students can benefit from the use of technology in ways that allow access to accelerated learning, like-ability peers, and other opportunities not otherwise provided in their school to support their pace and depth of learning. Access to appropriate supportive software and hardware, discussion forums, and online courses improves gifted students' reported interest, critical thinking skills, test scores, self-regulation strategies, and social interactions. In this way, technology does assist students in performing tasks based on their ability in ways that may not otherwise be available, especially if they are from geographically remote or under-resourced areas or homes where access to advanced opportunities are not available. As future research emerges in this area, perhaps definitions can continue to be expanded to look at students on both ends of the learning continuum. One cannot forget to include gifted learners, including those who are twice exceptional, as another population whose learning needs require assistance in order to fully invest in human capital and harness ways in which technology assists in performing tasks for which one is fully capable if provided the appropriate resources.

Attendance Marks

► Attendance Records, Educational Management

Attendance Records, Educational Management

Alan Strickley

CRIA Technologies, Harborne, UK

Synonyms

Attendance marks; eAttendance; Register; Roll book

Definition

Attendance can be defined as the physical or virtual presence at a learning environment either real or online. It can be measured as daily, morning/afternoon, or lesson based and has a variety of subclassifications as discussed in this entry.

Attendance is a key component of the educational management process as clearly learning can only occur when the learner is present in the learning environment and this normally requires attendance at a specific location. It may be mandatory through a legal framework or merely a requirement for the successful outcome of a course or exam.

Attendance records are a key part of all phases of the educational process from early years, primary, secondary, further, and higher education. They can take the form of handwritten documents, machine-readable records, biometrics, or automated through near field or similar technology.

Attendance can be recorded online, in person or by any other mode that indicates that the learner has been present in the learning environment.

However, it should be noted that although attendance may be linked to educational

advancement and learning in its most simplistic form, it has no necessary relation to this. While a student may attend 100%, they may not learn anything, while one who attends 0% may still pass a final exam. This, however, would not be true for some courses that require a minimum attendance to pass something which has an increasing popularity for educational institutions.

Recording Attendance

Historically attendance has been recorded by hand in a register or ledger. It is normally a legal requirement for statutory education although is likely to still be an institutional requirement where this is not the case.

In its most basic form, it is recorded as a binary mark either attended or not attended. However, a large number of additional statuses have evolved as reporting has become more prevalent.

For example, in England (DfE 2016), the USA (Marblehead Public Schools 2017), and New Zealand (Ministry of Education New Zealand 2015, attendance Code List 2015), the following are all used for various attendance types. These are shown in Table 1.

One of the obvious trends here is the number of different codes and absence marks that are available. This is often as a direct result of government reporting requirements as well as the desire for more management information made more accessible through the electronic collection and storage of attendance. In addition the distinction between authorized and unauthorized absence has also become prevalent as the reporting of truancy rates (unauthorized absences) has become more of an educational issue.

Since the year 2000 has started to be recorded electronically, this started with the use of Optical Mark Readers (OMR) in which preprinted register sheets are marked manually by the teacher and then fed into an OMR reader and the marks transferred electronically to a computer as shown in Fig. 1 (SIMS 2017).

However, as Strickley (2007) observes that although these forms were always filled in at the appropriate times, often they were not read into

the management information system (MIS) until the end of the day and at worst the end of the week. This meant the attendance records could not be used for truancy detection and prevention but merely as statistical records. This was, to some extent, due to the issues around the process of importing the sheets which could be quite time consuming.

The advent of whole school computer networks, Wi-Fi, swipe cards, and handheld appliances has meant that attendance can be recorded in real time at the point of entry into the learning environment enabling real-time recording, reporting, and remedy.

Finger prints and even retina scans have also been used for the purposes of recording attendance although there have been some legal and privacy issues here that make this method less attractive.

Key to any method is the requirement to cut down on administration in recording and the ability to monitor in real time.

To a greater extent, the advance of electronic attendance recording led to a more report-led model which in its own way created these complex attendance code systems as illustrated in Table 2 (Ministry of Education New Zealand 2015).

Legal Issues

In many countries attendance at schools is compulsory, enforced by law. As such the recording of attendance is a legal requirement, and the registers themselves are legal documents and therefore need to be accurate, secure, and held for a period of time. This requirement originally applied to manual records but now is applicable for electronic records as well.

In addition there are a number of statutory statistical and public reports that involve the use of these records and consequently their accuracy is paramount.

A result of the public publication of attendance records has, to some extent, resulted in the increase in the definition of absence above and beyond its original concept as illustrated in Tables 1 and 2.

Attendance Records, Educational Management, Table 1 Example attendance codes and meanings

Code (England)	Description	Meaning	Code (USA)	Description	Code (New Zealand)		
/	Present (AM)	Present	ABS	Absent excused	?	Not in class	Unknown reason
\	Present (PM)	Present	ABU	ABSENT- UNEXCUSED	P	In class	Present
B	Educated off-site (NOT dual registration)	Approved educational activity	ACI	ABSENT- CALLED IN	L	In class	Student is late to class
C	Other authorized circumstances (not covered by another appropriate code/description)	Authorized absence	COL	ABSENT- COLLEGE	S	Not in class	Sickbay
D	Dual registration (i.e., pupil attending other establishment)	Approved educational activity	DA	DISMISSED-ABSENT A.M.	D	Not in class	Medical appointment – doctor or dentist
E	Excluded (no alternative provision made)	Authorized absence	DM	DISMISSED- MEDICAL	I	Not in class	Internal school appointment
F	Extended family holiday (agreed)	Authorized absence	DP	DISMISSED-ABSENT P. M.	E	Not in class	or activity – dean, DP, sports administrator, coach, attendance officer, etc.
G	Family holiday (NOT agreed <i>or</i> days in excess of agreement)	Unauthorized absence	FT	FIELD TRIP	M	Not in class	Student absent due to short-term illness/medical reasons
H	Family holiday (agreed)	Authorized absence	GYM	OPEN GYM	J	Not in class	Justified absence – the reason is within the school policy
I	Illness (NOT medical or dental etc. appointments)	Authorized absence	HM	HOME and HOSPITAL	T	Not in class	No information provided – truant (or throw-away explanation)
J	Interview	Approved educational activity	LIB	LIBRARY	V	In class	Examination or unsupervised study – student is on the school site
L	Late (before registers closed)	Present	SIS	SUSPENDED- IN- SCHOOL	X	Not in class	Exam leave unsupervised study – student is off-site
M	Medical/dental appointments	Authorized absence	SOS	SUSPENDED- OUT-OF- SCHOOL	G	Not in class	Holiday during term time
N	No reason yet provided for absence	Unauthorized absence	SPD	SPORTS DISMISSAL	N	Not in class	On a school-based activity
O	Unauthorized absence (not covered by any other code/description)	Unauthorized absence	SRP	SENIOR PROJECT	Q	Not in class	Attending an off-site school – organized activity such as trip/camp

(continued)

Attendance Records, Educational Management, Table 1 (continued)

Code (England)	Description	Meaning	Code (USA)	Description	Code (New Zealand)		
P	Approved sporting activity	Approved educational activity	TA	TARDY-ABSENT- P.M.	W	Not in class	Work experience
R	Religious observance	Authorized absence	TD	Tardy dismissed	R	Not in class	Removed (temporarily) from regular class (internal school student isolation)
S	Study leave	Authorized absence	TDA	TARDY-DISMISS-ED- ABSENT	Z	Not in class	Secondary and tertiary program (including trade academies)
T	Traveler absence	Authorized absence	TEX	TARDY-EXCUSED- A. M.	O	Not in class	Justified overseas
U	Late (after registers closed)	Unauthorized absence	UTD	TARDY-UNEXCUSED	K	Not in class	Attending a teen parent unit
V	Educational visit or trip	Approved educational activity	UTR	TRUANT-UNEXCUSED	A	Not in class	Attending alternative education
W	Work experience	Approved educational activity	V	FAMILY ABSENCE	Y	Not in class	Attending an activity center
X	Non-compulsory school age absence	Not counted in possible attendances			F	Not in class	Attending an off-site course/ class
Y	Enforced closure	Not counted in possible attendances			H	Not in class	Attending a health camp/ regional health school/ residential school
Z	Pupil not yet on roll	Not counted in possible attendances			C	Not in class	Involved in justice court proceedings
#	School closed to pupils	Not counted in possible attendances			U	Not in class	Student is stood down or suspended

Attendance Records, Educational Management, Table 2 Attendance codes and meanings New Zealand

Attendance Code List 2015

Key	
Green	Present for half day calculations
Red	Unjustified absence
Blue	Justified absence

School Code	Classroom	Reason (Business Rule)	Explanations – The following explanations are provided as common reasons why a student may be absent from school. The Truancy Code column indicates if the absence is Justified or Unjustified. This does not preclude the Principal from using discretion over any specific student absence	Truancy Code	½ day calc
?	Not in class	Unknown reason (A temporary code)	This is the initial entry for a student not in class and the reason is unknown. It will be edited as relevant information becomes available about the reason for the non attendance. If required, the SMS can be set by the school to automatically change the "?" code to a T after a configurable number of school days (eg 7)	U	A
P	In class	Present	Student is in his/her regular class (This includes supervised study)	P	P
L	In class	Student is late to class	School policy will determine when this code is used. Eg. School policy may recommend that a student more than 10 minutes late is coded "L". Note this code does not contribute to the student's or school's absence or truancy rate	P	P
S	Not in class	Sickday	Student is known to be in the school's sickbay	P	P
D	Not in class	Medical Appointment – doctor or dentist	Current legislation means this type of absence is counted as present for ½ day summaries. There must be documentation verifying the appointment. This code is not to be used for a stay in hospital. Use code "M"	J	P
I	Not in class	Internal school appointment or activity – Dean, DP, sports administrator, coach, attendance officer etc	This can include students who are out of class for various school appointments including: form teacher, dean, senior management, counsellor, sports administrator, coach, nurse, carers, as well as students on an administration activity such as messenger, collecting attendance etc. It does not include a student who has been removed from his/her regular class and sent to the administration area for disciplinary reasons. This student would be coded P in the class and the code would probably be changed to R by the senior staff member dealing with the student	P	P
E	Not in class	Student is absent with an Explained, but Unjustified reason	The explanation for the absence is accepted by the school as the reason for the absence. But the reason does not fit within the school's policy as a justifiable reason to take the student off school. (Even though the parents may consider the absence was justified and may have provided a written explanation). E.g. "Molly had to stay home to look after her younger brother". For New Zealand and overseas holidays use code "O" – see below.	U	A
M	Not in class	Student absent due to short-term illness/medical reasons	Student is at home, or in hospital, because of illness or other medical reason. Depending on school policy a medical certificate may be requested for prolonged illness. eg three days, or as policy requires	J	A
J	Not in class	Justified absence – reason for absence within the school policy	Unplanned absences such as a bus breakdown, accident, road closure, extreme weather conditions etc Planned non attendance such as national/local representation in a sporting or cultural event in New Zealand or overseas Approved absence (including overseas) can also include bereavement, visiting an ill relative, exceptional family circumstances or a Section 27	J	A
T	Not in class	No information provided – Injured (or throw-away explanation)	An absence where either no information is provided, or the explanation is trivial (throw-away). I didn't feel like Maths so I took the period off - I had to finish an important assignment I went down to the river - I went to the shops - we had a test and I wasn't ready for it	U	A
V	In class	Examination or Unsupervised Study – student is on the school site	Students sitting examinations at school (if the SMS can provide attendance marking during exams) Unsupervised study – school process verifies student is on the school site. Note that supervised study is recorded as a regular timetabled class	P	P
X	Not in class	Exam leave Unsupervised study – student is off-site	Code X will count as a justified absence and contributes to ½ day absence summaries. Note that supervised study is recorded as a regular timetabled class	J	A
G	Not in class	Holiday during term time	When a student is on a New Zealand, or Overseas holiday during the school term, the absence is Unjustified. A parent's note does not provide justification.	U	A
N	Not in class	On a school based activity	A school-based (on-site) activity: cultural/sporting presentation/practice including swimming/athletic sports one to one tuition either as tutor or tutored	P	P
O	Not in class	Attending an off-site school-organised activity such as trip/camp	A school-organised off-site activity including overseas school trip (sporting, cultural or academic) school camp	P	P
W	Not in class	Work experience	Student is working for a recognised employer as part of their course (Gateway is an example)	P	P
R	Not in class	Removed (temporarily) from regular class (internal school student solution)	This code is for students who for a time period had an arrangement for alternative supervision. This may be in the administration corridor or in another teacher's class, instead of the student's regular scheduled class	P	P
Z	Not in class	Secondary Tertiary Programme (including Trades Academies)	The student is participating in a part-time (off-site) approved Secondary Tertiary programme that includes Trades Academies. The school is not entitled to be funded.	P	P
O	Not in class	Justified Overseas	A student accompanying, or visiting a family member who is on an overseas posting. (Up to 15 weeks) Eg military or diplomatic.	O	A
A	Not in class	Attending a Teen Parent Unit	The student is not in class, is on the school roll but funded elsewhere	J	P
A	Not in class	Attending Alternative Education	The student is not in class, is on the school roll but funded elsewhere	P	P
V	Not in class	Attending an Activity centre	The student is not in class but in an approved environment for which the school is entitled to be funded	J	P
F	Not in class	Attending an off site course/class	The student is not in class but is on a legitimate off-site school-based course	P	P
H	Not in class	Attending a Health camp/Regional Health School/Residential School	The student is not in class but in an approved environment for which the school is entitled to be funded	J	P
C	Not in class	Involved in Justice Court proceedings	Under existing legislation this type of absence is deemed to be Present when calculating ½ day summaries	J	P
U	Not in class	Student is Stood down or Suspended	Student is Stood Down or suspended according to the conditions of Section 14 of the Education Act 1989 (This code is for the period of the stand down/suspension. It does not include the day the stand down was imposed)	J	A

Key	
Green	Present for half day calculations
Red	Unjustified absence
Blue	Justified absence

Code not used: B
 Rules for Truancy Codes:
 J = Justified Absence
 U = Unjustified Absence
 P = Present
 O = Overseas (justified)

School closures

A Board of Trustees can close the school (for instruction) for reasons including:

- an emergency (earthquake, flood, etc); or
- strike closure

It is usual that ½ days lost do not have to be made up, but schools should confirm this when informing their local Education Office of the closure. The School calendar should be adjusted in the SMS to show such days (or ½ days) as a non-school day and this means the students' attendance cannot be marked. If the school's SMS cannot make a ½ day adjustment in the calendar, then students should be marked J (justified absent). In the case of a strike closure, although the school is closed for instruction, the Secretary expects boards to consider providing supervision for those students who do turn up. Note that Boards have ongoing responsibility for the safety of students while under supervision at the school, whether or not the school is also open for instruction

Keeping the school open

Depending on the circumstances the Board, while not closing the school, may ask parents to keep children (of specific, or all year levels) at home where possible, but if they send them to school they will be supervised. If the school remains open then students not attending are J (justified absent) and those attending are P (present).

Effectiveness

The electronic recording of attendance has had some significant effect on educational policy.

1. It has become one of the benchmarks of a successful school.
2. It has resulted in an expansion of the definition of absence.

3. It has to some extent resulted in a manipulation of absence as a result of 1.
4. It has resulted in legislation punishing parents who take their children out of school in term time.

Attendance reports are collected via the annual government censuses or equivalent and published at least annually.

In educational institutions such as further and higher education where attendance is not mandatory, the above have become less prevalent although are still monitored for the purposes of student satisfaction, etc.

Previous empirical literature indicates that student performance is inversely correlated with absenteeism. Studies in the USA (Roby 2004; Marburger 2010) would suggest that that attendance policies do improve performance. The authors investigate the impact of enforcing an attendance policy on absenteeism and student performance. The evidence suggests that an enforced mandatory attendance policy significantly reduces absenteeism and improves exam performance.

Reporting

As well as public and government accountability attendance data can be used within the institution to improve teaching and learning.

Firstly it is important that the data is available in real time and secondly that it is available in a management information system (MIS) that enables it to be linked to other collected data.

There are a number of ways that attendance data can be used in this way.

Using alerts the institution can be alerted to absences almost as soon as they occur.

The Future

In addition to the so-called am-pm attendance at the institution, the use of lesson attendance has become more prevalent in recent years. This can look at patterns of attendance within the day as well as detecting students who register at the start

of the day and then do not participate in any lessons. In addition it can be used to look at attendance in specific subject areas and with particular tutors as well as against gender age, etc.

Real-time recording and reporting with preset alerts can be an enormous aid to preventing unauthorized absence, and it can also be used to better allocate resources and track student patterns.

Summary

The recording of attendance has developed from a manual mark at the start of each morning and afternoon to a sophisticated electronic system using a multitude of codes to describe the type of absence recorded.

The increase in the publication of attendance particularly as a result of its collection through pupil-level census resulted in attendance records becoming a key indicator to the performance of an institution. In addition the role of attendance in the inspection process also increases its importance within educational institutions.

The use of attendance to manage the resources and management of a school is however still lacking in sophistication and development.

The future is undoubtedly going to see an increase in the recording of attendance both as a result of improved recording techniques and the desire for more management information. Whether this will result in an increase in performance remains to be seen.

Augmented Reality and Its Use in Education

Introduction

Educational content is increasingly being delivered through learning environments that are digital or technologically enhanced. One such technology-enhanced application is the evolving medium of augmented reality (AR), a technology that integrates interactive computer-generated data with the user's environment within a display interface. AR has the ability to enhance the real environment and perceptually enrich the user's experience, hence "augmented." This makes AR an enticing technology for educators to use as a tool since the real environment gets "annotated and informative" through the overlay of virtual objects in AR. Students construct new meaningful situational experiences with these augmented virtual objects that are brought to life in the backdrop of the real environment.

History of AR

The history of augmented reality spans over half a century. The term augmented reality was thought to be coined by former Boeing researcher Thomas Caudell who used this technology to assist in assembly of a jetliner in 1990 (Lee 2012). However, its first ever use was earlier in the 1960s, where Ivan Sutherland demonstrated simple wireframe drawings in real time via the first see-through head-mounted display (Lee 2012).

AR is used to display information that is beyond our senses which is used to guide us in the real world (Azuma 1997). Since the late 1990s, this ability attracted attention to utilize its potential and applicability in diverse fields

including commercial, maintenance, and education industries.

Virtual fixtures are one of the earliest functioning AR systems designed for the air force. A superimposed exoskeleton provides a guide to perform tasks from a remote space. In 1999, ARToolKit, an open-source software library for the creation of AR applications, became freely available to the public and revolutionized its accessibility (Azuma et al. 2001), thus allowing educators, trainers, and educational designers to be able to design AR objects and use them freely. This remains one of the most widely used libraries for current AR designs.

For training, the car manufacturer, Volkswagen, in 2013 started to use AR to assist their service technicians to foresee the repair process virtually on the physical vehicle. AR technology had remained in the purview of the corporate world; until in 2014, wearable AR devices for the public was made popular with the availability of Google Glass, thus making searchable information available “on the go” and contextualized to the perceived environment. Thereafter, AR applications have grown in leaps and bounds with AR and virtual reality (VR) investment reaching more than \$1.1 billion in terms of business importance.

Definition of AR

AR is defined as a technology that enables users to engage with virtual information augmented (usually superimposed) by computer-generated sensory input, e.g., graphics on the *live* direct or indirect view of a physical, real-world environment. This mediated immersion places digital resources throughout the real world, thus, augmenting the users’ experiences and interactions. Augmented reality is a subset of immersive technology that accounts for various computer-generated sensory information augmented onto the real world. Commonly, the sense augmented is usually sight but may be applied to other senses such as olfactory, haptic, and auditory.

AR is a system that possesses the following properties (Azuma et al. 2001):

1. Combines real and virtual objects in a real environment
2. Interactive and in real time
3. Registers (also aligns) real and virtual objects with each other

Thus to follow these criteria, not only do the virtual objects are to be placed in a real environment (e.g., as the virtual objects that were presented in the *Jurassic Park* movie) but also will these virtual objects need to be interactive to be considered as an AR (Azuma 1997).

AR belongs to one part of a spectrum of immersive technologies – the reality-virtuality continuum as illustrated by Milgram et al. (1994). At one end of the spectrum, as illustrated as the left side of the spectrum in Fig. 1 is the real environment – a physical space without any added virtual stimuli. At the other end is a world that is completely virtual with no involvement of physical elements.

The difference between augmented virtuality and AR is that it is more computer-mediated than AR as it adds real objects into virtual environment. Some examples of such real stimuli are such as texture mapping of videos onto virtual objects.

In the realm of AR, artificial intelligence is applied for its recognition of the “real world” to project the virtual information, thereby rendering virtual stimuli onto the real world and allowing user interaction. In contrast to VR, AR enables the user to experience real-life situations that are not readily or commonly accessible to the user (Rodriguez-Pardo et al. 2015).

Learning affordances of this form of mixed reality delivery of education include contextual skills development, tangible manipulation,

Augmented Reality and Its Use in Education,
Fig. 1 Diagram adapted from Milgram et al. (1994)

exploration, immersion, ubiquitous and situated learning, collaborative learning, reflection, analysis, and assessment.

AR Technology

The goal of AR is to integrate the computer's virtual object into the real environment or recognition of 3D virtual object space (objects, location, etc. within it) and so guiding the human user's visualization and knowledge of the same space. Because of this, AR requires enhancement of basic technology to create this complex integration. These enhancements are called enabling technologies, sensory interfaces, tracking system, registration of the virtual objects, and calibration to the environment (Azuma et al. 2001).

While various sensory interfaces such as auditory, haptic, and movement senses can be used, the interface most commonly in AR is visual displays such as head-mounted display, handheld display, or webcam-based displays. HMDs, which present a personal view of the AR environment, can be either optical or video displays. Optical displays are half-silvered mirrors with optical combiners to allow the augmented object to be seen in the real view of the user. Video displays on the other hand present a closed-view video that uses layering (chroma-keying) to augment the displayed video. These HMDs have their own advantages and disadvantages in terms of quality, immersion, and flexibility (Azuma 1997).

The commonest AR display devices are now handheld devices including mobile phones. The current high penetration of portable and mobile devices in the society particularly the younger audience makes ubiquitous learning and mobile learning with AR highly accessible to this crowd. Displays for AR are increasingly more powerful, compact, and portable making their availability more streamlined than before for wider user adoption (Lee 2012).

AR tracking can be designed as vision-based or sensor-based. Vision-based tracking can be further classified to *a priori* and *ad hoc*. An *a priori* system has prior knowledge of the object being tracked, and the most common example

of this as well as all types of tracking is marker-based tracking. Sensor-based tracking, on the other hand, utilises the GPS, magnetic compass, depth camera, inertia, infrared, or a combination of these technologies (Palmarini et al. 2018).

Use of AR Applications

AR is applied in a diverse range of fields and industries. The gaming market is one where it has found great success in. Some popular mobile applications include Pokémon Go; Temple Treasure Hunt; Zombie Go; Zombies, Run!; and Geocaching. These games have been instrumental in popularizing AR technology to the masses as well as introducing a large-scale social collaboration in AR.

In tourism, it can be used as a cultural heritage tour guide to display the view of the site prior to becoming ruins (Lee 2012). Museums can enhance the experience with viewing dinosaur fossils with augmented dinosaurs (Lee 2012). Art galleries use AR to display lost artwork.

The aviation industrial maintenance has used AR to reduce training time and error rates. An aviation maintenance inspector requires 2000 hours to become trained (Palmarini et al. 2018). The complexity of aircraft systems allows AR to be the preferred training method compared to traditional teaching. By reducing eye and head movements, allowing the user to skip the paper manual and concentrate the task at hand, AR reduces time and error rate in complex maintenance operations, thus improving profitability.

In sports, applications such as PoolLiveAid use AR to guide players in pool game with visual aids. It estimates the direction of where the ball will go and displays this in real time as the player can interactively adjust their aim to the visual cues.

AR is applied in the healthcare in a diverse range of fields including rehabilitation, physical medicine, psychology, psychotherapy, and mental health. AR's interactivity becomes an advantage when being used as a patient education tool. Weghorst as cited by Azuma et al. (2001) describes AR to rehabilitate people with Parkinson's disease suffering from an akinesia. In

the treatment of phobias, AR is used for subjects to transfer acquired skills in therapy to the real world (Riva et al. 2016).

AR in Education

By bridging the gap between the virtual and physical world, AR has revolutionized our conventional teaching methods. There are now many emerging applications of AR for use in digital classrooms. As an example of its use, Google Sky Map is a planetarium application to teach astronomy when viewing the night sky.

Of the various subjects and fields, AR is most commonly applied in the field of sciences at 40.6% (Bacca et al. 2014). Though the target group of most research on AR application is mostly students of bachelor's or equivalent level, various AR games have been successfully designed for school-going students.

Some examples of AR games for early years of learning include an AR system for K-12 students to learn means of transportation (Lee 2012), a virtual space in AR for learners to collaboratively construct geometric shapes for K-12 students to learning geometry (Lee 2012). In physics, AR objects with various kinematic properties were created for learning through their estimated visualized results in real time (Lee 2012).

An exciting application of AR is the concept of "magic books" where the information presented through books are integrated with AR. These are similar to the 3D pop-up book, but, instead of physical viewing and interaction, 3D models are rendered virtually in an AR display.

Numerous literatures on anatomy learning in AR have been published for target groups ranging from children to medical students. These applications typically superimpose organs onto the user's body or a friend's body. Similar to virtual museums with lost artwork, a repository of anatomy learning objects in the laboratory is designed as an AR museum for medical students to explore.

In the higher education sector, AR can be used to simulate field work and even work-based learning (WIL). For example, in the medical

field, clinical experience is highly regarded for medical and health professionals to form core competencies with the consideration of patient safety. A pilot work by the authors developed presentation of clinical signs in AR to facilitate physical examination (Sen et al. 2017). Preliminary data has shown potential in authentic learning of clinical skills without posing risks to patients. In spite of numerous published articles, AR's role as a supplementary method of delivery in education remains as a huge potential that needs to be explored further.

Potential Benefits of AR

For a generation of learners more technologically fluent than ever, AR holds great potential in enriching their learning. AR applications offer a very efficient method to deliver small bite-sized learning content for students. Such small chunks of content through AR can be used to explain a topic and augmenting information on a pre-existing learning topic (Bacca et al. 2014).

In educational research, AR has been the subject of study by educators for its impact on learner. Commonly studied measures to evaluate AR in education are learning gains, motivation, engagement, and collaboration. In general, most studies indicate improvement in learning outcomes. AR has been found to have positive effects on conceptual thinking, interaction with others, and cognitive load. Objectively, this was evidenced by a study that found improvement of performance (by 53.5%), motivation (by 28.1%), and engagement (by 15.6%) with use of AR (Bacca et al. 2014).

In another study, students learning about solar systems through AR were found to achieve greater scores compared to conventional learning methods. Similarly, students learning about parts of the aircraft turbine engine through AR showed improvement in short- and long-term retention of information. This was consistent with another study that used AR to teach word pictograms using more detailed information in comparison to desktop conditions. Compared to pre-existing level of achievement, learning gains in AR

learning modality were higher in low to average achieving students and thus had a more impact than on high achievers (Radu 2014).

Game-based learning increased the learner's engagement and significantly found greatest positive impact in less academically successful students (Lee 2012). Another study found that game-based learning promoted student collaboration in solving tasks in K-12 mathematics, language, and scientific literacy (Dunleavy et al. 2009).

Educational Theories in Relation to AR

Various theoretical underpinnings have been put forward to explain the impact of AR in education. One of them is the conceptual blending theory that describes how, in AR, the combination of virtual objects with real objects within a real space gives new meaning to the learner. In AR, the dynamic physical qualities of the visual presentation may become the focus of the learner's attention because of the learner's control over the content. Teaching children astronomy in different mediums found that children use different ways to conceptualize content. In AR, children learned to identify planets based on movements, while in PC presentation, children focused on details and visual look of the planets (Radu 2014).

Constructivism is a learning paradigm that encompasses an active, contextualized process of constructing rather than acquiring knowledge, based on personal experiences and the environment. Constructivism accounts for the learner playing an active role in connecting theory and application by interacting with the AR content that creates both an engaging personal experience as well as interactive environment. Being actively involved through AR can provide experiences in a novel way toward authentic (real-life) scientific inquiry (Zhu et al. 2014). Some examples are the "Alien Contact" AR project where students could act "like a real scientist" when solving situational puzzles and medical education AR applications where transfer of knowledge to real-life situations was achieved by learning the orientation of superimposed human organs even

if mistakes were made (Dunleavy et al. 2009; Radu 2014; Sen et al. 2018). The students found the experience with the AR environment to be a personalized and explorative experience for themselves (Zhu et al. 2014).

Reduced cognitive load may be an explanation of improved task performance. In repair and maintenance on military tanks, workers performed faster with fewer head movements (Radu 2014). Puzzles with AR instructions had faster completion time with fewer steps (Radu 2014). In healthcare training, AR decreased the amount of practice toward proficiency and reduced failure rates in real life (Zhu et al. 2014). In relation to Mayer's multimedia learning theory, this could be explained by the spatial and temporal contiguity effect. AR can present the information within the same plane in the real environment, while temporally, AR presents information closely with a physical phenomenon to allow an association to form (Radu 2014). This real-time interactivity has been found to provide a focused guide for users to learn more effectively (Riva et al. 2016).

Enhancing the learning experience with whole-body interaction using AR relates to the concept of "embodied cognition." "Embodied cognition" links the conceptual understanding of the abstract concept with physical activity such as gesturing or hand movements (Radu 2014). Inputs to the AR experience enhance skill proficiency in a range of motor skills, hand coordination, hand-eye coordination, fine motor, and gross motor (Radu and Macintyre 2012). The enhancement of the learning experience with tactile, audio, and visual cues is a form of multisensory integration.

In experiential learning theory, the shared experience from coordinating a mixed reality space with learners becomes meaningful to the student. When students perform such a shared activity such as navigating a map together in AR, students experienced more effective collaboration with greater retention and motivation in the learner (Radu 2014), a typical example of the experiential learning theory.

Affective reactions, such as enjoyment and pleasure, toward the immersive technology

support the “flow theory” (Suh and Prophet 2018). AR environments can create strong engagement between the narrative and real world. This may explain how unmotivated students transform to become highly engaged. Students can become willing to play the game repeatedly out of pleasure as they enjoy the challenge of graduated difficulty in these AR games (Dunleavy et al. 2009). This is driven by their internal goals as well as the balance between challenge and their goals (Radu 2014). Furthermore, some of the AR GPS-based games can allow students to express creativity and environment exploration. Higher enthusiasm in learners in turn produces higher satisfaction ratings.

Challenges in Using AR for Education

While the AR tools in creating an immersive educational experience are advancing rapidly with the betterment of technologies, there are still limitations of current AR technology. The development of AR content in AR involves both high cost and considerable time. Although open libraries (e.g., open CV, open GL, MATLAB) and software development kits (SDK) are freely available to facilitate its programming design, most of them are based upon mid-to-low-level programming languages (e.g., C++, C#, Java, HTML, CSS, etc.). These programming aids are not yet user-friendly for the public at large and still require highly skilled people to utilize them in creating AR systems.

AR applications for education are designed to enhance specific learning tasks and thus to customize to the educators needs; many of these well-designed AR applications still need to be created from scratch rather than through ready-made templates. Thus, the process still requires visual designers, 3D artist, and games/AR designers rather than it being in the purview of sole educator. Visual designers are also involved in designing presentation of the information within the AR applications. Some, though not all AR objects are 3D models superimposed on the real environment, and this 3D modelling requires skills in

design software applications such as Catia, Blender, and 3Ds Max; therefore, a 3D artist may be sought making the AR applications of good quality but expensive to produce. Creating AR-based games will also require collaboration with game designers (Palmarini et al. 2018). Due to its intricate development phase, direct access to author content is not yet accessible to educators (Bacca et al. 2014).

Creation of accurate realism of content is limited by current image capture technology. Video blending limits the user’s view to the capability of the cameras but may lack realism altogether (Azuma 1997). Human eye can adapt to six orders of magnitude of light, but brightness determines the eye pupil size which in turn also determines the depth of focus. Current display technologies like using the pinhole model show that all objects are in focus regardless of distance (Azuma 1997). Furthermore, displays may also adapt poorly to the real environment causing errors in depth perception (Azuma et al. 2001). In comparison, if the environment is too bright or dark, the virtual object is immediately identified as virtual. Accommodation-vergence conflicts in the eye, low resolution, and inaccurate lighting cause the virtual object to appear further away. Over time, users adapt to this displacement and exhibit large overshoot in real-life performance (Azuma et al. 2001). Further development in graphics is needed to simulate better match depth and real distances as in a human eye (Azuma 1997).

Other anticipated issues with AR are mostly related to technological failures. Time learning could be lost due to either GPS failure, software instability, or incorrect setup of the system. GPS failure could be as high as 30% which could be also complicated by environmental factors such as weather extremes that may prevent GPS-based outdoor-based AR activities (Dunleavy et al. 2009).

To avoid the challenges of GPS-based AR, majority of educational AR projects opt for marker-based AR for ease, stability, and less complex tracking. Furthermore, open libraries offer more readily available marker-based AR with more technical support (Bacca et al. 2014).

However, marker-based tracking suffers greatly from registration issues. The tracking algorithms depend heavily on the marker's position, orientation, and visibility which are frequently affected by weather and wear (Palmarini et al. 2018). Frequently, common tracking algorithms track poorly causing frustration to users (Bacca et al. 2014). It is challenging for input devices with low frame rates like webcams to depict quick gestures, thus resulting in interrupted interactions in AR (Radu and Macintyre 2012).

Registration error occurs when the system is unable to accurately track the desired object seamlessly. This triggers motion sickness to the user due to conflicts in the human senses. For example, a visual error occurs when the user perceives the virtual hand at the wrong distance over the real hand (Azuma 1997). Temporal latency also contributes to registration error. The interactive nature of the AR medium dictates that the system must respond to the user's unpredictable actions. Registration latency causes static and dynamic errors where objects remain still or move inappropriately (Azuma 1997). The augmented information is delayed resulting in reduction of task performance (Azuma et al. 2001).

Apart from the software issues as described above, there could be challenges in usage of the hardware. Hardware displaying AR can be the source of physical discomfort to the users. An example of this is the "tunnel vision" due to the limited field of view of some displays that may even aggravate motion sickness (Radu 2014). Such a limited field of view also interferes with team interaction and collaboration (Bacca et al. 2014). Prolonged exposure to display screens causes fatigue and eye strain to the user, also known as computer vision syndrome (Azuma et al. 2001). Repetitive strain injuries resulting from bending or sustaining postures for long periods of time also occur (Radu and Macintyre 2012).

Limitations in the hardware can also pose challenges in AR design. A study found that younger children would typically hold the device with both hands because the device is too heavy for one hand. This interrupts their live interaction in the session as they had to place it down before moving the markers. Some types of displays

also limit the physical space for exploration, counteracting benefits of gross motor training (Radu and Macintyre 2012).

Though AR applications appear to aid visualization, the use of AR systems and hardware can counterproductively increase cognitive load (mental activity exerted on the working memory). These systems are quite complex to set up, and configuration of the head-mounted display to the platform itself can be complicated and time-consuming (Radu 2014). An education session utilizing more than a single type of device to access the content also contributes to high cognitive load (Suh and Prophet 2018). Some students may become overwhelmed by the amount of AR content for use within a short time span (Dunleavy et al. 2009). High requirements of support and management from technical staff raise the question of how feasible AR curricula are on a large scale. Teachers, working independently in classroom situations, find it challenging to support and troubleshoot the technicalities of the AR activity without support from technical staff (Dunleavy et al. 2009). Despite these difficulties, students remain highly motivated to learn how to use the new technology (Radu 2014).

Distracted attention occurs when students ignore important parts of the learning task (Suh and Prophet 2018). Similar to how in assembly task training, workers tend to ignore previous errors and proceed to complete the task with poor recall of the errors made (Suh and Prophet 2018), in AR game-based learning, students may become focused on "winning the game" and ignore the steps in solving the problem, thus resorting to guessing or copying another person's answers to "win." This is also described as attention tunneling (Radu 2014).

Features of novel technology, such as AR can distract the students. An infrared function of an education session caused them to fail to complete the learning task (Bacca et al. 2014; Dunleavy et al. 2009). Distraction is also aggravated by teacher domination in the session (Suh and Prophet 2018). Limited number of displays also makes participation difficult, and students no longer pay attention to the session. In this way, the benefits of AR technology are no longer at

play because students are ignoring the real environment.

Distracted attention outside the classroom can be dangerous. Studies featuring GPS-based tracking found students too engrossed with the game space and lose awareness of the real environment (Suh and Prophet 2018). They were guided back to safety when wandering into traffic area (Dunleavy et al. 2009).

Studies found negative cognitive reactions to immersive technology and presumably, toward AR as well. Demographically, immersive technology is less well-received with the female gender and older age groups (Suh and Prophet 2018). Personal attributes like high sensation-seeking tendency and poor personal innovativeness also contribute to poor response to mixed reality technology (Suh and Prophet 2018).

In comparing AR with VR, AR has fewer graphic requirements because of fewer virtual objects to render. In addition, realism can be compromised in goals of AR; thus, high-quality graphics are not necessary. Lower-resolution and monochrome images can be used (Azuma 1997). For example, to outline a workflow, simple lines can be used to demonstrate the desired design.

In terms of tracking, AR requires a higher registration and representation fidelity (Suh and Prophet 2018). These errors are very easily detected in an AR environment. VR is more forgiving. This is because in VR, “visual capture” causes the user to eventually adapt to the systematic errors from prolonged exposure. While in AR, “visual capture” would not be beneficial in the goals of most AR applications as accuracy is key for translation of skills to the real world (Azuma 1997).

Future of AR in Education

It has been predicted that global research, education, and training by 2030 and beyond will witness a prime focus on the AR/VR industry and its applications. With the advent of social media having drastically changed how people interact with each other, its platforms are a potential avenue for

incorporation of learning with mixed reality (D’Angelo 2017). As technological advancement will overcome some technical difficulties highlighted earlier, AR will become not only more ingrained as part of everyday life and social platforms but will be more ubiquitous and more accessible to all (Suh and Prophet 2018).

With the markerless AR technology growing, development of new algorithms to identify forms can resolve major issues associated with markers (Bacca et al. 2014) which will make use of AR universal and not limited by connectivity. Trends show that new computer-aided design models can potentially overcome registration and tracking issues. By extracting features of the virtual object and comparing with the image of the real object, the real object is identified through the image being captured by the camera. This technology attempts to overcome lighting issues, one of the greatest challenges in AR technology (Palmarini et al. 2018).

Further research on AR in the field of education is on the cards. Research is focusing on novel technologies with computer vision and motion sensing capabilities that allow users to interact with the digital environment with greater immersion than before. For example, an interactive performance system for dance learning measures visual and sonic aspects of gestures by a system called action graph. This system enables mapping of gestures with desired augmented generation of functionalities, thus enhancing dance training interactively (Iqbal and Sidhu 2017).

Types of studies on AR are also expected to change. There is yet large-scale educator-led AR-based curricula in place. Larger study sample sizes will be possible once developer tools and AR hardware become more accessible. Further studies are still needed to identify curricular-specific and technology-specific characteristics that contribute to learning (Dunleavy et al. 2009).

Evaluation methods on impact of AR applications are presently mainly qualitative in nature and need to be diversified to include more quantitative measures on user experience (Suh and Prophet 2018). As AR is becoming more ubiquitous and no longer remains a novel educational tool, studies that compare AR with non-AR

delivery of education cross-sectionally need to extend their focus to longitudinal studies to identify long-term effects on learning once its novelty has worn off (Palmarini et al. 2018). Such research will help reveal the genuine positive learning impact of AR technology apart from its novelty effect.

There is a need for more studies of impact of AR application on diverse groups of students. Target groups of educational AR are mainly of students at tertiary level of education and of scientific backgrounds (Bacca et al. 2014). AR applications' ability to support learning should not be limited to those already in an educational institution. Further studies can provide more information on its applicability to other possible target groups in other fields such as vocational studies, art, language, psychology, and therapy (Suh and Prophet 2018). Another identified potential target group is the use of AR for special needs students (Bacca et al. 2014). Multimodal applications can be used as therapy for sensorial and physical impairment. VR has been found to be effective in aiding autistic people to cope in social situations (Riva et al. 2016). In mixed reality settings, AR can potentially create inclusive educational settings for people with special needs (Bacca et al. 2014).

Types of content suited for AR are being explored extensively to match the appropriateness of the content to the design of the AR. As an example, topics that rely heavily on abstract thinking may be difficult to be designed and taught via AR, while visual-based content may be more suited for AR delivery. Further studies are ongoing to measure the learning benefits of these identified types of content objectively. As raised by several studies, AR will likely be complement to education delivery not a substitute (Azuma 1997; Rodriguez-Pardo et al. 2015).

As discussed earlier, low-achieving students found greater learning gains with AR compared to high achievers. To be inclusive and benefit both ends of the student cohorts, further customization is needed to create content appropriate for a range of pre-existing level of achievement. The creation of tools for educators to author content and personalize to the learner's needs

is another facet that has yet to be addressed. Only a few (2 out of 32 studies) identified in a literature search found some personalization process (Bacca et al. 2014). Ideally, future research will identify the differences in learning gains when tailored to the audience's needs.

Social acceptance is an important factor to be studied to determine whether wider use of AR would be feasible (Azuma et al. 2001). For example, what society thinks of AR will affect how likely a user would wear a head-mounted device in a public area. As current applications are still in the prototype phase, data on market penetration remains to be fully gathered (Zhu et al. 2014). However, its acceptance will improve vastly as AR is gradually being integrated to everyday life and is being seen both as an educational tool as well as a platform for social interaction.

The application of AR in education has opened up new vistas in learning paradigm such that the current and future designs of AR in education may need guidance from learning theories. AR applications have opened up new possibilities than what the present traditional learning strategies can afford. Design guidelines for human-computer interactions exist and can be the building blocks for future AR design guidelines. These guidelines will also need to be field-specific (Zhu et al. 2014). Due to AR's nature of being highly hardware dependent, its applicability is being given due to the consideration to the learners' age group which may dictate the type of hardware used in its particular learning needs, especially, as previously discussed, where younger age group user struggle with handheld devices (Radu and Macintyre 2012). Identifying the limits of AR applicability is crucial for educators to select appropriate content to teach in AR. With considerations of current gap of research in AR, guidelines for effective designs of AR-based educational experiences can be proposed (Radu 2014; Bacca et al. 2014).

Conclusion

AR has been gaining ground since its first use almost 50 years ago. With its expanse of potential benefits, AR integration in education has been

evolving and increasingly widespread especially now that mobile platforms are so easily accessible. As an effective supplement of education delivery, AR has been found to increase visualization, interactivity, and knowledge content. Many beneficial AR factors on education have been identified though more detailed studies are needed to examine their long-term relationship to learning. In order for AR to reach its full potential in the field of education, further studies as well as technological advancements are necessary. It has been raised consistently that guidelines are needed to aid in the design of AR-based learning environments. Learning theories have been identified and require further application in the development of these guidelines.

Augmented Reality: Definition and Features

Augmented Reality: General Idea

Augmented reality is a technology that has gained popularity in recent years; it is often referred to in the subject literature as an emerging technology that has great potential for educational activities. This technology is based on the idea of applying an additional layer of digital information to images of real objects and locations in real time, thus complementing and extending them with new, additional elements that are valuable to the user (Azuma et al. 2001). The additional layer of information can contain text, images, videos, or other multimedia or interactive components that expand the view of the physical world with digital elements. The main features that distinguish augmented reality from other technologies include seamless blending of virtual and real elements into one environment, giving users the ability to interact with this environment in real time, and providing accurate 3D placement of virtual and real objects (Azuma et al. 2001). The aim is to provide the user with a visually attractive and cognitively rich information transmission of a hybrid nature that combines physical and digital environments (Barfield 2015). Augmented reality is already widely used commercially in business and entertainment, but it is also finding applications in the services of cultural institutions and more often in educational activities and their promotion.

Augmented Reality: Technical and Practical Conditions of Use

On the practical side, the use of augmented reality requires the use of a mobile device, usually a smartphone, tablet, or special goggles. The application of the digital layer to the physical environment of the user can take place in two main ways: based on geolocation options the mobile device sends information about the user's location to the application, and this information is compared to a database of digital objects assigned to this location (this is the principle of many augmented reality games or the popular Layar search engine), or with the use of special markers (so-called

beacons) that can be located in space and contain encoded information read by the mobile device's cameras, as is often used in custom applications created for a given company or institution (Geiger et al. 2014; Sato 2017). Digital information can be displayed in a "head-up" model that displays information directly in the user's line of sight, on transparent surfaces such as special glasses, or in the case of applications for pilots or drivers, on a vehicle's windscreen. This type of presentation has many benefits because it allows information to be received naturally, without the user having to look away and at the mobile device; this is especially important in applications designed for people who must simultaneously follow the physical environment and the hybrid environment of augmented reality. Digital information can also be displayed in a "head-down" model which displays information on a traditional mobile device such as smartphone or tablet; this is a popular solution due to the widespread availability of mobile devices and their ease of use (Smith et al. 2017).

In the context of the practical aspects of the application, attention should be paid to three things that can significantly influence the quality of the message provided through augmented reality. The first factor is the technical parameters of the mobile device on which the application is viewed. Smoothly combining the physical and digital realms requires the device to have sufficient memory capacity and a fast network connection. The functionality and user-friendliness of the application itself are also very important: the service must be intuitive, easy, and pleasant for the user so the information can be delivered effectively (Tsai et al. 2016). The third factor is the information and media literacy of the user: receiving information in hybrid environments such as augmented reality requires competence in the field of multimedia processing and the ability to understand cognitively rich messages, which may not be easy for everyone.

Augmented Reality Versus Virtual Reality: Similarities and Differences

The concept of augmented reality is often discussed in the subject literature alongside the topic of virtual reality, which may raise questions

about the similarities and differences between these technologies. As explained earlier, augmented reality is based on combining digital and physical environments; specifically, on the image of the real world, a digitally generated information layer is placed which enriches the general message with new and relevant elements. As a result, the user can see physical and digital objects and information at the same time. Virtual reality, on the other hand, is based on the idea of immersing the user in an artificial digitally generated world and cutting off external stimuli from the real world. The goal is to give the user the impression of being in a 3D world that may or may not resemble the real world (Kipper and Rampolla 2012). Virtual and augmented reality are therefore two different concepts that should not be confused, but they are often discussed together in the subject literature because of the popular concept of the so-called virtuality continuum that was described in the 1990s by P. Milgram and F. Kishino. These authors presented a scale in which at one end there is the real world, at the other end there is virtual reality, and between there is what is referred to as mixed reality, which includes augmented reality. Virtual and augmented reality are thus found together on the scale of the virtuality continuum; hence they are often discussed together. However, they differ from each other essentially: virtual reality is a completely artificial digital environment, whereas on the virtuality continuum scale, augmented reality is close to the world of physical objects (Milgram and Kishino 1994).

Augmented Reality in Education: Current Scope of Use

Augmented Reality in Early Education

Augmented reality, due to its multimedial and visually attractive character, is used at early stages of education to increase children's motivation and attract interest in learning. Augmented reality is practically used, among others, to teach children simple motor skills: for example, pointing, moving, or catching objects; coordination, memorization, recognition of colors and geometrical

shapes, simple language skills, information, and media literacy skills; as well as basic competences in various educational subjects such as mathematics, biology, or languages (Salvador-Herranz et al. 2013; Solano et al. 2017). According to G. Salvador-Herranz et al., using AR in the education of preschool children led to "students showing greater attention in class, accompanied by a notable interest in the subject being taught" (2013, p. 37). Augmented reality can also be used as an educational tool to help build ethical competences and awareness, such as responsibility in the field of pro-ecological behavior (Bodén et al. 2013), road safety rules (Lugmayr et al. 2018), as well as soft skills related to collaboration and working in teams.

To summarize, augmented reality can be used at the entry level of education to teach core physical, intellectual, and emotional competences and more specific knowledge in different educational subjects, as well as to build social competences, attitudes, and behaviors. The interactive and multimedial nature of the message and its visual attractiveness can help motivate children to learn and help them build early, positive experiences related to education.

Augmented Reality in Middle-Stage Education

At the middle stage of education, augmented reality is widely used in teaching various subjects, especially those that are stereotypically seen by students as difficult or tedious, such as mathematics, physics, chemistry, geography, or history (Cai et al. 2014; Estapa and Nadolny 2015). It increases their motivation to learn, improves memorizing processes, and increases the level of understanding of the given subject. Similarly, as in the case of primary education, at middle school, and high school levels, a beneficial effect of using augmented reality on educational processes can be observed. Evidence for this can be found in the results of research carried out by S. Cai, X. Wang, and F. K. Chiang, who showed that using augmented reality in teaching chemistry has a positive influence on chemistry education among middle school students, especially low-achieving ones (2014). Similar results can be found in a

paper by A. Estapa and L. Nadolny, according to whom the use of augmented reality in mathematics education clearly increases students' level of motivation to learn this subject (2015). It is worth noting that research is always conducted on a specific group of students and often shows that the influence of augmented reality differs between different groups (for instance, more able students vs. less able students) and different subjects, but generally it seems the use of augmented reality has a positive effect on students' learning experience and their motivation to study, which may translate into greater achievements in understanding and remembering a subject's content.

Augmented Reality in Higher Education

Augmented reality is widely used in many fields of higher education, in particular science, biology, chemistry, and medicine. It is a valuable tool for visualizing information that allows students to deal in an accessible way with complex models, projects, and layouts. This is particularly useful to students of physics, chemistry, architecture, or engineering as it allows them to visualize phenomena and/or design complicated systems (Akçayır et al. 2016); it is also useful in the fields of biology and medical sciences for memorizing large amounts of knowledge, for instance, to study human or animal anatomy (Moro et al. 2017). Some research showed a positive effect of the use of augmented reality on students' cognitive processes in the field of medicine. Research conducted by S. Küçük, S. Kapakin, and Y. Gökteş showed, for instance, that using an augmented reality application when studying anatomy reduces the cognitive load yet yields higher learning achievements (2016). This thesis can also be confirmed by research conducted by C. Moro et al. that showed the great effectiveness of virtual and augmented reality as tools for learning anatomy in the field of medicine; they provide an engaging, interactive environment for studying and increase students' motivation and enjoyment (2017). Analogous results have also been shown, among others, in research conducted with students of physics. M. Akçayır et al. showed that using an augmented reality app can significantly

help students to develop their laboratory skills, as well as to build positive attitudes toward physics laboratory classes (2016).

As in the case of learning at entry and middle levels, students can also use augmented reality to learn personal and social skills such as the ability to study effectively. According to research by J. Martín-Gutiérrez et al., augmented reality facilitates collaborative work among students and creates an environment for autonomous learning (2015). Augmented reality is used not only by students of science and medicine but also by students of humanities and social sciences, such as history, communication, linguistics, or art. Research conducted by J. A. Delello, R. R. McWhorter, and K. M. Camp on a group of students of marketing, human resource development, and education showed that for all three disciplines, augmented reality is a useful tool for learning that creates a positive experience for students and encourages them to learn (2015). The use of new information and communication technologies such as augmented reality may positively affect the motivation to learn, as well as support students' creativity, the ability to understand cause-and-effect processes, as well as develop empathy and other moral values.

Augmented Reality in Adult Education

Nowadays, education lasts a lifetime, and many adult people who are professionally active want or need to continually improve their education. Augmented reality can also be applied to work-related adult education, for instance, during training or courses. Analogously, as in the stages of education discussed previously, in adult education augmented reality can be used both to build specific professional skills characteristic of different professions, as well as to build general personal and social competences, such as group work skills, work planning, and time management, and to increase motivation to work. Augmented reality is used, among others, in applications supporting the repair of vehicles by mechanics or in applications for professional drivers, pilots, engineers, architects, and designers. There are not many papers exploring this topic; however, based

on the promising results of studies from the higher education sector, it can be assumed that augmented reality may also be useful in processes of lifelong learning and self-improvement of adult learners.

Augmented Reality in Special Education

A very important aspect of the usefulness of augmented reality is its use in the education of people with various types of disabilities, most often emotional, intellectual, cognitive, and sometimes also physical (Richard et al. 2007). There is a lot of research related particularly to the usefulness of augmented reality in the education of people (especially children) with Asperger syndrome and autism at various stages (Escobedo et al. 2014; Nazaruddin and Efendi 2018; Syahputra et al. 2018). Research has shown that augmented reality can help people with autism spectrum disorder (ASD) to better focus on tasks, which is crucial for knowledge acquisition processes in various disciplines. Augmented reality can also be helpful in the process of developing social skills, such as understanding situational contexts or recognizing body language and emotions (Escobedo et al. 2014; Syahputra et al. 2018). Research conducted by C. Chen, I. Lee, and L. Lin clearly showed, for instance, that “through repeated ARSFM training, adolescents with ASD can more accurately recognize and more appropriately respond to the emotional facial expressions they see in everyday social situations. This augmented experience can increase the ability of people with ASD to understand others’ emotions and improve the assessments of emotional expression and social skills of adolescents with ASD” (2015, p. 402). Augmented reality can also help in recognizing objects (Nazaruddin and Efendi 2018), which can be useful in learning many subjects that require the manipulation of shapes and their location in space, including mathematics and physics. All in all, augmented reality can be used in the education of people with special needs as a tool to help them focus attention, better understand models and spatial relations of objects, and increase general social skills, as well as motivation to learn.

Main Areas of Augmented Reality Use in Education: Summary

Summing up, it can be concluded that augmented reality is used at various degrees of the education of children, teens, adults, and those with disabilities, to support the development of various groups of competences in science, medicine, humanities, and social sciences. The subject literature analysis shows that augmented reality may help in the development of spatial imagination, visualization and understanding of models, decision-making skills, critical thinking, and understanding of processes (including social and historical). Augmented reality also helps in the formation of language skills (particularly foreign language learning), the ability to discuss and work in groups, as well as in the development of general imagination and creativity (Wójcik 2016). Importantly, using augmented reality in the process of learning often increases students’ enjoyment, satisfaction, and motivation in the subject being taught. As J. Bacca et al. conclude, augmented reality is particularly effective as a tool for “better learning performance, learning motivation, student engagement and positive attitudes” (2014, p. 146). Of course, not all research results clearly show a high-quality difference in teaching with the aid of augmented reality. Bearing in mind that many factors contribute to the final effect of education, in the process of assessing the influence of augmented reality on education, it is important to take into consideration the target group, the subject being taught, the teacher’s competence, and the quality of the application itself. However, it seems that the majority of studies show the great utility of augmented reality for teaching and learning.

Augmented Reality in Education: Benefits and Risks

There is no doubt that the use of augmented reality in education has many advantages. First of all, it is an innovative technology that can be used to transfer knowledge in a new, attractive way that increases motivation to learn and helps build

positive learning experiences. The engaging and visually appealing multimedial character of the message arouses interest and willingness to learn in both children and adults. As has been shown, augmented reality may increase the effectiveness of education in many fields and at different levels of education, including the education of people who are struggling with intellectual, emotional, or cognitive problems. However, as with any innovation, there are certain dangers that must be remembered. Some authors conducting research in pedagogical sciences and psychology point out that cognitively rich environments such as augmented reality can overwhelm the user and cause feelings of confusion, stress, impatience, or information overload (Wu et al. 2013; Bower et al. 2014). According to Wu et al., “There are also challenges related to learners and their learning processes. In an AR learning environment, students could be cognitively overloaded by the large amount of information they encounter, the multiple technological devices they are required to use, and the complex tasks they have to accomplish” (2013, p. 47). As Bower et al. conclude, “(…) utilization of technology is by no means a guarantee of success. On the contrary, poor use of emerging technology can result in inferior learning outcomes” (2014, p. 12). The use of augmented reality in itself does not bring educational benefits but only serves as a tool for achieving didactic goals and must be used correctly in order to tap potential and minimize risk. One often-mentioned risk factor is the need for users of augmented reality to have specific competencies that enable effective use of this technology. The use of applications based on augmented reality requires, for instance, a specific level of technical knowledge that enables smooth operation of mobile devices and apps. A systematic review of the subject literature conducted by M. Akçayır and G. Akçayır showed, for instance, that some of the biggest challenges that may discourage students when using augmented reality in the classroom are related to technical problems and the usability of applications (2017). For the effective implementation of augmented reality, it is therefore necessary to have good quality electronic equipment, well-designed applications, and

the competences for their proper use on the part of students and teachers. In addition to technical competences, it is also very important to take into consideration students’ level of competences in the field of information and media literacy. The ability to selectively receive information shared in cognitively rich environments is necessary to fully benefit from the potential of augmented reality. These competences should ideally be represented among students, teachers, and parents but at least among teachers so they can assist students. This is especially important when working with the intellectually, emotionally, or cognitively disabled, as was pointed out, among others, by M. A. Nazaruddin and M. Efendi in the context of using augmented reality applications to teach people with autism (2018).

The use of new information and communication tools in educational processes is often also hindered by practical problems related to the need to purchase appropriate equipment and applications, which can be expensive when providing for large groups of students. Using augmented reality applications also requires constant updating of equipment and teachers’ knowledge in the form of training, all of which can be very expensive. The downside of using augmented reality in education is therefore the need to incur regular financial expenses which may be beyond the financial capacity of many schools.

Summing up, it can be concluded that using augmented reality as an educational tool has both pros and cons. The risks and negative aspects of using this technology can mostly be neutralized by rational planning of the role of new technologies in the educational process and costs related to their use, as well as by equipping students and teachers with the competences necessary for the effective and responsible use of augmented reality.

Augmented Reality in Education: Potential for the Future

The positive effect of using augmented reality on the teaching of competences has been proven in many areas, but many have not yet been

examined, and, as emphasized by Wu et al., in comparison with research on the use of other tools in education, for example, the Internet or multimedia, research on the effectiveness of the application of augmented reality is still in the early stages (Wu et al. 2013). Augmented reality is, however, mentioned in many publications by both scientists and practitioners in various fields as a so-called emerging technology that will develop and become more and more popular in the future (Bacca et al. 2014; Ponce et al. 2014; Ozdamli and Hursen 2017). According to F. Ozdamli and C. Hursen, “Augmented Reality is a developing technology which has the potential to influence the teaching–learning process” (2017, p. 122). A similar opinion is presented in a paper by C. S. C. Dalim et al., according to whom “Integrating AR in education may lead to a brighter future for the educational sector. AR has the potential to engage students in a better learning experience that could create a more comprehensive teaching and learning process” (2017, p. 586). Based on these predictions, it seems that incorporating augmented reality into educational processes is a wise decision; however, much depends on the level of acceptance of this technology by students, parents, and teachers. Research carried out so far in this area is rather promising. A study conducted by A. Balog and C. Pribeanu showed that the perceived usefulness and enjoyment of using augmented reality tools in education are factors which greatly affect the level of acceptance of this technology among students (2010). C. S. C. Dalim et al. identified six factors that influence the acceptance of augmented reality: the balance between the technical and pedagogical aspects of an augmented reality application; the reliability of an augmented reality app; a student’s ability to use augmented reality independently without help from teacher or parent; the ability to include others in the process; students’ individual features and background; and the platform used to deliver augmented reality (2017). Knowing the factors that influence the adoption of new technologies can facilitate their widespread introduction and encourage the belief that augmented reality may have great potential for educational activities in the future.

Conclusions

Augmented reality is already widely used in various stages of education, in different age groups, and to shape various competences. The cited studies show the possibilities of the effective application of augmented reality in the education of children, adolescents, and adults in many areas: history, geography, biology, medicine, mathematics, physics and chemistry, languages, motor and spatial skills, object recognition and coordination, and social competences such as working in groups or autonomous learning. Importantly, many studies indicate that the use of augmented reality not only increases the efficiency of learning specific knowledge or competences but also increases students’ satisfaction and motivation to learn, all of which helps to create a positive educational experience.

In summary, it can be said that augmented reality is applicable everywhere that it is important to visualize complex processes, procedures, or objects or to increase students’ level of motivation and enjoyment when learning subjects often considered difficult or tedious. Augmented reality’s full range of applications in education is not yet known, but it seems that this technology has great potential. However, as with any innovation, it is important to maintain a reasonable approach and implement new solutions gradually to avoid possible negative effects that often accompany the use of technology in education, such as cognitive stress or information overload.

Beginnings of Computing in School Education in Australia

Arthur Tatnall
Victoria University, Melbourne, VIC, Australia

Synonyms

Computer science; Information technology;
Primary schools; Secondary schools

Introduction

In the early 1970s, a small number Australian schools began to get involved in computing, typically resulting from the exposure of maths/science teachers to computing during their university courses. The way computing was typically introduced was through the teaching of programming by the school's mathematics department. Early examples included a PDP-8 computer in one Victorian secondary school and an 8 k Wang computer in another, each paid for through a Commonwealth Schools Commission "Innovations Grant." The schools used teletype terminals with paper tape readers and accessed the computers via dedicated telephone lines. This arrangement was, however, soon seen to be not very satisfactory.

The next step was in 1974 with the introduction of MONECS (Monash Educational

Computer System) that typically ran on a DEC PDP-11 (DEAMON) minicomputer and used mark-sense cards for program and data entry (Monash Computing Museum 2003). This technology was also typically used in schools' mathematics departments for the teaching of programming in FORTRAN or BASIC. The students filled in the cards at their school using a pencil, and then their teacher delivered a batch of the cards to a local university for execution. The results were often disappointing for the students as in many cases all they got back was a printout listing a number of syntax errors. It took some students several tries to get a program working properly.

This then had very little overall impact on school education. It was the arrival of the microcomputer, and especially the Apple II in 1977, that saw the beginnings of real advance in the use of computers in education.

The Arrival of the Microcomputer

The late 1970s and early 1980s saw a huge increase in the number of low-cost microcomputers on the market and available to schools. These microcomputers included Apple II, Tandy TRS-80, Commodore VIC-20, Commodore-64, Acorn BBC, MicroBee, Atari 400/800, Cromenco, Osborne, Sinclair ZX80, XZ81 and Spectrum, Sorcerer, Altos, Franklin ACE, DEC Rainbow, Hitachi Peach, SEGA,

The Usual Procedure for Loading Tapes

1. Make sure your computer is in Applesoft BASIC
2. Rewind the tape
3. Start the tape playing
4. Type LOAD
 After you press RETURN the cursor will disappear. Nothing happens for from five to twenty seconds, and then the Apple beeps. This means that the tape's information has started to go into the computer. After some more time (depending on how much information is on the tape, but usually less than a few minutes) the Apple beeps again and the prompt character and the cursor reappear.
- 4a. If you got an error message such as ERR , the tape did not LOAD properly. Turn your computer off (with the switch in the back), and begin the process again at step one.
 NOTE: You cannot recover from a LOAD error by using RESET.
5. Stop the tape recorder and rewind the tape. The information has been transferred, and you are finished with the tape recorder for the time being.

Enjoy your new Apple!

Beginnings of Computing in School Education in Australia, Fig. 1 Loading tapes (Apple Computer Inc. 1979a)

Amstrad, Spectravideo, Apricot, Micromation, Pulsar, and Olivetti.

Of these, the Apple II, Commodore-64, Acorn BBC, and MicroBee became the most commonly used in Australian schools. These were relatively low-cost computers. At around \$2,000 for a 16 k Apple II that used a tape drive (not supplied – you had to use your own cassette recorder) and a television set (you also had to supply your own) as a monitor, the Apple II was almost affordable for most schools.

The IBM PC and Apple Macintosh did not appear in Australian schools until the mid-1980s. This made the need for some form of computer systems evaluation by state computer authorities most important (Tatnall and Jenner 1986). Australia is a federation of states, each having a considerable degree of independence. In education, the role of the Commonwealth Government is limited to one of coordination, leadership, and the funding of specific projects. School education is the direct responsibility of the states.

It is interesting to look at a page from the instruction booklet that came with a demonstration tape for an Apple II in 1979 to see what a

person taking delivery of their first computer might need to deal with (Tatnall and Davey 2008) (Fig. 1).

Later that year the first disk drives appeared, and a Word Processor program could be obtained from Apple. Advice from the instruction booklet (Fig. 2 below) was all in friendly caps (as most printers did not then have lowercase):

Once this “simple” procedure was undertaken, the instructions assure the user that *almost nothing could go wrong* with the program except if they had done something silly like pressing the Reset Key or typing in “too many lines” (see Fig. 3 below).

Computer Awareness and Other Uses in Secondary Schools

Once a school had purchased a computer, the question was what would you do with it? The obvious answer was to teach programming, but another idea that was to emerge was teaching a “Computer Awareness” subject. In Victoria in 1980, the McDougall report to the Education

RUNNING UP THE SYSTEM

AFTER SWITCH ON AND AFTER INSERTING THE WORD PROCESSOR DISK IN THE DISK DRIVE, TYPE 'G'; THEN HOLD DOWN THE 'CTRL' KEY WHILE PRESSING 'P'; THEN PRESS 'RETURN'.

WHEN THE DISK HAS STOPPED RUNNING THE SCREEN WILL DISPLAY AN INTRODUCTORY MESSAGE. TO CONTINUE WITH THE PROGRAM PRESS ANY KEY.

Beginnings of Computing in School Education in Australia, Fig. 2 Word Processor disk instructions (Apple Computer Inc. 1979b)

WHEN YOU HAVE FINISHED WHAT YOU WANT TO TYPE IN, YOU CAN TYPE 'END' AT THE BEGINNING OF A LINE. ON PRESSING 'RETURN' YOU WILL BE PRESENTED WITH A 'TRAFFIC DIRECTORY' TO HELP YOU CHOOSE WHAT YOU WANT THE PROGRAMME TO DO NEXT.

PLEASE NOTE –

IF SOMETHING GOES WRONG WITH THE SYSTEM DURING THE TIME YOU ARE ENTERING TEXT, IN MOST CASES THE PROGRAMME WILL RESCUE YOU FROM DISASTER. VERY RARELY, THE SYSTEM WILL GO HAYWIRE AND YOU WILL BE PRESENTED WITH AN ASTERIX (*) AND A SERIES OF UNINTELLIGIBLE NUMBERS. THIS IS DISASTER INDEED. YOU WILL HAVE TO START ALL OVER AGAIN. FORTUNATELY THE OCCURRENCE IS RARE. THE MOST USUAL CAUSE IS THAT YOU HAVE PRESSED THE 'RESET' BUTTON. USUALLY YOU WILL BE RESCUED. THE CAUSES OF THE PROBLEM ARE THESE –

1. YOU HAVE RUN OUT OF MEMORY,
2. YOU HAVE TYPED IN TOO MANY LINES.

IF YOU HAVE RUN OUT OF MEMORY OR HAVE TYPED TOO MANY LINES, SAVE THE FILE AT ONCE. YOU CAN BREAK IT INTO PAGES AND JOIN IT UP WITH OTHER FILES LATER. THE MAXIMUM NUMBER OF CHARACTERS IS ABOUT 12,000 AND THE MAXIMUM NUMBER OF LINES IS 200.

Beginnings of Computing in School Education in Australia, Fig. 3 Word Processor instructions (Apple Computer Inc. 1979b)

Department Computer Policy Committee noted that: “Computers have been called electronic ‘brains’ and there is no doubt that in the popular view, they are surrounded by an aura of mystery and are credited with powers they do not possess. The result is that most people outside the computing profession have attitudes of awe and fear towards computers and feel helpless and powerless in a highly computerised society” (McDougall 1980: 3). There is, of course, now no need to make students *aware* of computers and what they can do, but at this time computers were an unknown novelty. A typical Computer Awareness subject taught in a secondary school might include discussion of:

- How a computer works, computer programming, history of computer technology
- Business and commercial uses of information technology
- The social implications of increased use of computers

Subjects like this made use of the school computer (often an Apple II) to give the students some hands-on experience and quickly became popular with the students who were intrigued by the new computer. It was also seen as worthwhile by their parents, many of whom saw the possibility of better jobs for their children if they learned how to use these new machines. These subjects remained

in place in many schools until the late 1980s (Computer Studies Curriculum Committee 1983; Tatnall and Davey 2006).

It was not long before several different streams of Computer Education emerged in Australian schools:

- Computers across the curriculum – computer use in different subject areas
- Computer Science
- Programming in mathematics
- Use of Word Processors by secretarial studies students
- Logo
- Computer industry/business training in technical schools (Tatnall and Davey 2004)

State Computer Education Centers

In its 1983 report “*Teaching Learning and Computers*,” the Commonwealth Schools Commission (1983) sums up the early formation of computer education centers in Australia:

Education Departments in some states introduced computing into their schools before microcomputers became plentiful and inexpensive, by installing a minicomputer in a central place and using it to provide a service to schools. Having made this decision it was essential that a Centre be established with staff to operate the computer and provide support to teachers who were using it.

This comment refers in particular to South Australia and Tasmania which commenced programs of Computer Education (mainly of computer programming) earlier than the other states.

The South Australian Education Department had a policy on School Computing Activities which indicated that: “computing is an object of study in its own right, computing provides the means of enhancing and extending traditional components of the school curriculum and computing and related technology have the potential to change the curriculum, the manner in which that curriculum is implemented and to improve the general organisational procedures used by schools” (Shears and Dale 1983). In 1968 it sets

up the Angle Park Computing Centre which provided schools with a batch card-input system for teaching computer programming. It also produced curriculum materials and educational software.

Tasmania introduced a Year 12 Computer Studies course in 1972 and developed a state-wide time-sharing network for educational purposes. In the mid-1970s, it sets up the Elizabeth Computer Centre to develop educational and administrative software for the network and for microcomputers and the provision of advice and training to Tasmanian teachers.

The other Australian states and territories all got seriously involved in Computer Education after the intervention of the Commonwealth Schools Commission.

Assistance from the Commonwealth Schools Commission

In 1983 the Australian Government sets up the *Commonwealth Schools Commission National Advisory Committee on Computers in Schools (NACCS)*, to provide leadership and funding for Computer Education across all Australian states and territories (Tatnall and Davey 2008). “The widespread availability of a variety of hardware has opened up opportunities for school use of computing that have not previously existed” (Commonwealth Schools Commission 1983). In the period 1984–1986, the *Commonwealth Schools’ Commission Computer Education Program* provided \$18.7 million for coordination of Computer Education facilities and financial offerings in each of the states. The NACCS report *Teaching, Learning and Computers* listed a number of possible uses for computers in schools:

- Computer Awareness/Computer Literacy courses in upper primary and lower secondary schools
- Computer Science/Computer Studies/Information Processing
- Using computers across the curriculum
- Curriculum support including preparation of teaching materials and student records

- Communications with other teachers, students, and remote databases
- Administrative applications for database management and financial management

Computer Education Consultancy

An important school curriculum support mechanism used by many states in the late 1970s and 1980s was the Subject Consultant. These consultants were practicing school teachers who were seconded, usually on a part-time basis, and were chosen for their subject expertise, teaching ability, willingness to adapt to and lead educational change, and ability to get on with and work with other teachers. Unlike most other subject consultants, Computer Education Consultants were pioneering a new area of education and had little in the way of established precedent, techniques, or materials to assist them (Tatnall and Davey 2008). The task of the Computer Education Consultants was thus to introduce and offer suggestions on the use of computers in schools. They would run professional development activities, demonstrate educational software and discuss its possible classroom use, consult with individual teachers and school principals, and investigate possible school administrative computer applications (Tatnall and Davey 2012).

State Recommendations of School Computer Systems

The late 1970s and early 1980s saw a huge increase in the number of low-cost microcomputers on the market and available to schools. There was no way that each state computer education center could offer support for such a large range of computers, and so some recommendation and control process were necessary (Tatnall and Jenner 1986). In each state computer education center, a process of evaluating computer systems (both hardware and software) for educational use was undertaken regularly, and as a result, a “Recommended List” was set up, and

government schools were obliged to purchase only *recommended systems* with Education Department funds.

In 1985 in Victoria, the recommended computer systems were Apple IIe, Apple Macintosh, BBC Master 128, BBC model B, MicroBee, IBM JX, and Pulsar and in NSW, MicroBee, Apple IIe and Macintosh, BBC model B, IBM JX, Tandy 1000, and Sperry PC. In other states and territories, Apple IIe, BBC model B, MicroBee, and Commodore-64 were common recommendations.

The Australian Educational Computer

A longer-term proposal by NACCS was for the development of an “Australian Educational Computer” that would reinforce Australian culture with Australian software and be built in Australia by an Australian company. Several other countries including the UK, New Zealand, Sweden, and Canada had already decided to design and build their own school computers, and it seemed worthwhile for Australia to also do so. There were several reasons for a project to develop a computer of this type in Australia (Tatnall 2013):

- So that Australian school children would have access to well-designed computer equipment.
- To reduce the problem that US-designed computers such as the Apple II and Commodore-64 came with the burden of imposing aspects of American culture.
- To provide a development and manufacturing opportunity for Australian industry. It was generally supposed that an Australian company such as MicroBee, which produced a CP/M computer used in many Australian schools, would be a likely manufacturer.

To begin the project, NACCS sets up working parties for an **Educational User Requirement** and an **Educational Technical Requirement** to develop the computer. The Department of Science and Technology would then have produced a **Systems Concept Study** and **Australian**

Design Specifications (Commonwealth Schools Commission 1983), but at this stage the project stopped (Tatnall 2013, 2014). The 3-year government initiative for the National Computer Education Project was at an end and so was its funding. Perhaps it was a good thing that the project to build the Australian Educational Computer did not continue, as at this time the dominance of the IBM PC and the Apple Macintosh began. Had the project continued it may have created a white elephant like the ICON from Canada that was compatible with neither the PC nor the Apple Macintosh. Today the decision Australian schools make in choosing which type of computer to use is between a Windows PC and a Macintosh.

Computing in Australian Schools in the 1980s

In 1981 Computer Science was first offered as a Year-12 subject in Victoria. Most other states then also began offering Computer Science courses, typically in the last 2 years of secondary school. Computer Science courses usually involved the study of algorithms, programming in a language like Pascal, and understanding a little of the machines that carry out these procedures. They also offered some discussion of computer use and the social implications of computer use.

By the mid-1980s, uses of school computers for other than teaching programming were widely acknowledged, and computers were now beginning to be also used in other subject areas. The firsts of these subject areas were mathematics and commerce. There was some use of computer-based simulations in general science and of databases in other subjects including social science. Australian schools never did go very far down the line of Computer-Assisted Instruction (CAI).

One important application, especially in some primary schools, was the use of the programming language Logo that involved using commands like FORWARD 10 and RIGHT 90 to move a “turtle” around the screen. (Logo could be used for other programming tasks and was related to

Lisp) This was made more interesting to students by the use of a “turtle robot” that could be made to move around the floor. These robots were available from a number of overseas companies, but the one most used in Australia was the locally built “Tasman Turtle.” In the late 1980s and early 1990s, Lego produced a robotics kit, Lego Technics Control, that made use of a programming language rather like Logo and was used in some schools.

The use of computers for educational administration in schools began to grow from the mid-1980s. This typically began by local school teachers writing programs for things like managing the school sports and later programs to produce student reports and record attendance. By the mid-1980s, state education authorities began producing their own administrative packages to manage school finances and facilitate school reporting.

By the late 1980s, the teaching of secretarial studies moved to use of word processing programs, and commerce teachers began making serious use of spreadsheets. Despite being involved at the beginning, computer use by maths teachers was now in decline. At this time, with the relatively small number of computers in each school, conflict arose on how best they could be used. The conflict was between those who thought that teaching *about* computing was important and those who thought that only the *use* of computers in subject areas in schools was worthwhile.

Computing in Australian Schools from the 1990s to Today

By the late 1980s and into the 1990s, the large variety of microcomputers had vanished, and the PC and the Macintosh had been taking over.

The use of email began to grow rapidly in the late 1980s, and with the arrival of the World Wide Web in the 1990s, schools began to make use of the Internet (which earlier was text-based and quite difficult to use in schools) skyrocketed. Schools quickly found plenty of uses for this technology in many applications.

In recent times perhaps the biggest change has been the availability of mobile computing through the use of mobile phones and tablet computers such as the iPad. Some primary schools now proscribe the purchase of iPads by students in Grade 3 to use both at school and at home.

One of the latest developments is the teaching of “coding” which is claimed to assist with “computational thinking” that is seen as “a fundamental set of skills that all students need to be prepared for the future real-world challenges.” A Lego kit encourages the use of coding using its building bricks with the intention to “encourage students to explore, build, code, test and refine solutions to engaging STEM (Science, technology, engineering, and mathematics) challenges”(Lego Education 2016). Scratch (from MIT Media Lab) is also used in a similar way by some schools.

Conclusion

In the 1980s Computer Education was seen in the category of a *special* curriculum area. Its removal in the 1990s to become a normal part of the school curriculum reflected its coming of age. Far from being the novelty as it was in the 1970s, the use of computers in all types of schools for all types of applications is now commonplace.

Birth of Information Systems Curricula in Victoria in Colleges of Advanced Education and Universities

Arthur Tatnall
Victoria University, Melbourne, VIC, Australia

Synonyms

[Business computing](#); [Computer science](#); [Information technology](#); [University courses](#)

Introduction

Eighty years ago there were no stored-program electronic digital computers in the world. Even 50 years ago, a computer was something that few organizations could afford and few people could use. Suddenly, in the 1960s and 1970s, everything changed and computers began to become accessible. This created a big need for education in different forms of computing. Today the need for education in Information Systems (sometimes called Business Computing) is generally acknowledged with each university in Australia offering courses of this type. What happened to promote the adoption of such courses in Victoria is the subject of this article.

The first real electronic computers were built in the 1940s by engineers and scientists for military

and research purposes. In designing machines like ENIAC in the USA and Colossus in Britain, little heed was paid to possible commercial applications: it was during World War II, and the need was military and pressing. A major purpose behind the design of ENIAC was to solve the differential equations required for the calculation of ballistic trajectories. At the same time in England, Alan Turing, a pioneer in the theoretical foundations of computing, worked on Colossus, a special purpose computer adapted toward Boolean logic and designed for the task of breaking enemy codes (Winston 1986).

Early Computing in Australia

There are today two main approaches to the teaching of computing at the university level: those of *Computer Science* and of *Information Systems* (or *Business Computing*). But apart from both being based on the study of a particular machine, how are such courses related? It is tempting to think that perhaps as Computer Science came first, courses in Information Systems evolved from these as the *applied* version of computing. A study of the origin of computing courses, however, shows that this was not the case and that courses in Information Systems in Australia had origins quite different from those of Computer Science.

Australia made its move into electronic digital computing quite early. Trevor Pearcey and Maston Beard built the CSIR Mk1 (CSIRAC) in the late 1940s for the Commonwealth Scientific and Industrial Research Organisation (CSIRO). It was Australia's first internally stored-program computer and the world's fourth. From 1948 to 1956, it was located in the University of Sydney. In 1956 it was moved to Melbourne and set up at the CSIRO Division of Radiophysics in the University of Melbourne where it remained in service until 1964 (Pearcey 1988).

It had now become quite clear that it was necessary to create university courses in computing. The fact that it was the CSIRO, with its connections to the universities and to government, that led the way into computing in Australia

probably assisted in the early introduction of computing courses in Australian universities. Trevor Pearcey, prominent in building CSIRAC, joined the CSIRO Division of Radiophysics in Sydney at the end of 1945 where he worked for some years. In 1947, during his time at Sydney University in the Department of Mathematics, he introduced what was Australia's first university course in computing: *The Theory of Computation, Computing Practices, and the Theory of Programming*. This course was an early one and was offered before CSIRAC became operational in 1948 (Tatnall 1993).

Early Computer Science Courses

From the mid-1950s onward, a number of university computer systems were opened to general use, and practical training in programming and the application of computers was introduced at the Universities of Melbourne, Sydney, and NSW. Early training courses, of a few weeks duration, were offered in the techniques of programming appropriate to each machine. At that time, of course, to use a computer *at all* really required knowledge of programming. It was, however, some time before education in computing was seen anywhere other than university departments of statistics and mathematics. Programming courses were given regularly in the University of Melbourne from 1956, and in 1959 a formal subject in *Numerical Methods and Computing* was developed by Pearcey as part of the undergraduate BA course in pure mathematics. Undergraduate courses in the *Theory of Computation* commenced in 1964 with the establishment of the Department of Information Science (Pearcey 1988).

The study of statistics is a field which has always required knowledge of mathematical and computational processes, and up till the 1950s, university departments of statistics provided such knowledge. Departments of mathematics tended to ignore numerical mathematics and considered advanced numerical skills to be somewhat undignified. To some extent this attitude was to continue as a resistance by the

educational establishment to the new Computer Science, arguing "that it was not an academically well-founded discipline" (Pearcey 1988). It was not until the early 1960s that the universities accepted that Computer Science was a different discipline to mathematics.

Early Business Computing Courses

Before the entry of the digital computer, punched card accounting machines were used by many businesses, and early courses in their use were offered by the suppliers. By the 1930s the accounting machine had evolved into a quite sophisticated electronic calculator capable of performing complex arithmetic tasks and of processing dozens of punched cards per minute. Early courses in the use of accounting machines in Victoria's Technical Colleges introduced students to concepts including formal analysis of problems using techniques such as those of Organization and Methods (O&M) (Organization and Methods may be defined as the systematic and objective examination of an organization and its detailed methods of working in an endeavor to gain increased efficiency.) and Systems Analysis, as well as introduction to the concept of programming (Maynard 1982). They also prepared the ground for later Business Computing courses.

At a computer conference in Sydney in 1951, Trevor Pearcey was apparently asked "Do you think these things will be of any use in the commercial business area?" to which he replied with an emphatic "No!" (Philcox 1978). Pearcey believed that "you would not waste expensive computing resources on such mundane things as business computations" (Maynard 1990).

Entry of the Commonwealth Government

Once computer technology had been developed, the practice of computing was first put into serious use by the Commonwealth Government in the early 1960s with the requirements of the Commonwealth Public Service Board for large

numbers of computer professionals to staff its administrative computing projects in the Department of Defense and in the Postmaster-General's Department (PMG). A big problem though was that there were not enough of these qualified computing personnel. This was further aggravated by commercial projects beginning to be undertaken in large companies such as BHP, CRA, CSR, the banks, and the airlines. (Because of the cost of computers at the time, it was only large companies and the government itself which could even consider their use.) All these commercial projects required systems analysts, systems programmers, and application programmers who were in very short supply and commanded very high salaries. Feasibility studies took years to complete; long periods were taken up with planning, tendering for hardware and operating system software, selection of suppliers, installation, and formal acceptance. Supply delays of 1–2 years were normal. Getting computer professionals from overseas was not easily possible either as a number of other countries were in a similar position.

There was an urgent need for training, and the 4-week courses of a manufacturer, coupled with knowledge of the job in the firm, were not considered sufficient qualification. What was needed were courses with a substantial component that was vocational in nature, and the universities seemed uninterested in providing these being more interested in theoretical Computer Science.

The solution was that the Commonwealth Public Service Board (PSB) should provide leadership in course provision and that control of the training function should be centralized (Philcox 1978). The training needs of these projects were the main spur to the introduction of courses in Business Computing in tertiary institutions in Australia and in Victoria in particular.

The Programmers-in-Training Scheme

In 1960 the Board ran its first courses in *Analysis and Design of Mechanised Systems* and *Systems Analysis and Design* for its middle management

officers. These courses involved 12 weeks of full-time training, both theoretical and practical, and were conducted at the PSB's Automatic Data Processing (ADP) Training Centre in Melbourne. Course content included:

Introduction to systems analysis and design	1 week
Basic programming	5 weeks
Equipment characteristics	1 week
ADP systems analysis and design	5 weeks

Regarding its 12-week training as successful in providing "crash computing courses" in computing, the PSB recognized a need to set up longer courses and began designing a full year long *Programmer-in-Training* (PIT) course. The first PIT course ran in 1965 and initially drew upon the defense staff's experiences with both computerized and existing noncomputerized administrative systems. The PIT courses took over 20 h per week of formal class time for a year and operated initially in Canberra and Melbourne but later also in other capital cities. An outline of the 46-week course was:

Phase 1 (10 weeks)	
Introduction to the Course and to the Service	1 week
Computer equipment and techniques – Stage 1	1 week
Computer mathematics – Stage 1	1 week
Programming – Stage 1	5 weeks
Systems analysis and design – Stage 1	1 week
Examinations	1 week
Phase 2 (12 weeks)	
Departmental training – Stage 1	
Phase 3 (12 weeks)	
Computer equipment and techniques – Stage 2	1 week
Programming – Stage 2	4 weeks
Systems analysis and design – Stage 2	4 weeks
Mathematics – Stage 2 (statistics)	2 weeks
Examinations	1 week
Phase 4 (12 weeks)	
Departmental training – Stage 2	

The programming part of the early PIT courses started off with a study of machine code and then moved to assembly language before finally getting down to Business FORTRAN which was a

very powerful language developed by Control Data. Later, studies of COBOL and PL1 were also introduced (Maynard 1990). A problem was that programming and operating systems differed between different makes of computer system, and equipment suppliers each had an entirely different approach to computing that also needed to be considered when designing Systems Analysis courses. Although there was no formal syllabus for Phases 2 and 4, the Commonwealth Departments who took on trainees were required to prepare, in advance, a program for each trainee. This program had then to be submitted for approval by the Public Service Board (Grainger 1967).

PIT courses continued under the Commonwealth PSB until late in the 1960s when responsibility transferred completely to the tertiary education sector: to several of the newly formed Colleges of Advanced Education (CAEs). These PIT courses set the style for many of the courses later offered in the CAEs and Institutes of Technology. Although a number of Australia's universities had access to computers during the 1950s and some had even begun to take the teaching of Computer Science seriously, during the early to mid-1960s, they were both unready and unwilling to take up the challenge of turning out what they regarded as people with "vocational training" in computing. It was the Colleges of Advanced Education and Institutes of Technology which began to develop these courses. From that point on, a discipline of *Computing*, which was wider than Computer Science and was soon to encompass what we now call Information Systems, began to develop.

Courses in Colleges of Advanced Education in the 1970s and 1980s

One of the first educational institutions in Australia to adopt computing as a priority teaching area was the (then) Caulfield Technical College (Later Caulfield Institute of Technology and then Chisholm Institute of Technology) in Melbourne. As early as 1961, Caulfield had

offered a *Certificate of Accounting (DP)* course and by 1964 a number of short, evening, post-diploma courses in various aspects of computing: *Punched Card Systems*, *Accounting Machine Applications*, *Commercial Electronic Data Processing*, and *Principles of Analogue Computing*. Maynard (1990) reflects that in both Australian and worldwide terms, these courses were very early: "people were still teaching accounting machines – IBM punch-card machines. They were trying to move from punch-cards into the computing arena, but IBM was very slow in really getting computers into business." Braverman (1974) explains that learning to use punched card machines involved the equivalent of an apprenticeship where a period of learning was done on each type machine and the programming (wiring a panel board for each machine) done at this time was "simply the highest skill of an all-around trade." Juliff (1990) reports that in tertiary institutions, the equipment-based subjects of the 1960s typically spent roughly equal amounts of the time discussing accounting machines, punched card machines, and computers.

At Caulfield in 1964, the new *Diploma of Information Processing* was aimed at educating students "... in the operations and capabilities of data processing equipment as well as an appreciation of the principles involved in technical and commercial applications of this equipment" (Greig and Levin 1989). In 1967 the *Diploma of Business Studies (Data Processing)* commenced as a forerunner of many later courses in Business Computing.

In 1970 the Commonwealth Public Service Board handed over the running of the Programmer-In-Training course to four selected institutions, Caulfield Institute of Technology, Bendigo Institute of Technology, Canberra College of Advanced Education, and New South Wales Institute of Technology, as it "... believed that the increasing use of sophisticated computer equipment at the colleges and their need for increasing numbers of trained 'computer personnel' made such a development desirable" (Greig and Levin 1989). In 1971, the first year of operation of the "new" PIT program, the scheme

supported 235 trainees Australia-wide (Philcox 1978). This new scheme had the wider objective of providing trained computer personnel to industry as well as to the Commonwealth and State Public Service. Although similar in content to the early PIT courses, those delivered by Caulfield Institute show some maturation:

Phase 1: Ten weeks, 9 am–5 pm, Monday–Friday, at Caulfield Institute	
Computer Mathematics, Problem Logic	2 weeks
Data representation, computer equipment	1 week
Principles of programming	3 weeks
Applications programming	4 weeks
Phase 2: Twelve weeks of on-the-job training in present organization	
Phase 3: Ten weeks, 9 am–5 pm, Monday–Friday, at Caulfield	
Statistics and quantitative analysis	2 weeks
Systems programming	3 weeks
Data communications	1 week
Systems analysis and design	4 weeks
Phase 4: Twelve weeks of on-the-job training in present organizations	

In the early 1970s, Caulfield introduced the first commercial computing degree in Australia, the *Bachelor of Applied Science (EDP)*, that was later renamed *Bachelor of Applied Science (Computing)* with the primary goal of “developing computer professionals for employment in government and industry” (Greig and Levin 1989). During the mid-1970s a joint course combining the core elements of the *Bachelor of Applied Science (Computing)* and the *Bachelor of Business (Accounting)* was instigated as this was conceived as being of value to both students and prospective employers, as students completing it gained accreditation from both the Australian Computer Society (ACS) and the Australian Society of Accountants (ASA). From this time many other CAEs around Australia began developing similar courses in Business Computing. Also in the 1970s, many courses began to move students off the use of punched cards and onto terminals, but this was a slow operation taking 10 years to complete. Minicomputers could still be run on cards, and it took quite

a while for some institutions to be weaned off them. “Cards were much more concrete: you could take a pack of cards with you” (Juliff 1990).

University Computing Courses from the 1970s

Typically university Computer Science courses were initially sponsored by Mathematics Departments, and there was resistance to this new subject from many of the other mathematicians (both pure and applied) who saw Computer Science as just another kind of mathematics. Most universities saw computing in terms of mathematical Computer Science with little or belated attempt to relate to business or industrial applications. At the University of Melbourne, for example, under considerable outside pressure at the time the Department of Computer Science introduced COBOL and Systems Analysis courses to make its students “employable,” Melbourne seemed to be little interested in teaching about the commercial uses of computing and so contributed little to this area (Wilde 1992).

In other universities some attempt was made to make Computer Science more practical. At La Trobe University, Woodhouse (1992) describes how in the 1970s it was a “constant battle to get the purists to accept Computer Science as a significant study in its own right.” A Department of Computer Science was set up at La Trobe in 1978. In 1977 at La Trobe University, the *Graduate Diploma in Computer Science* took its first intake of students. Not wanting to create a course in *academic* Computer Science of the type offered by Melbourne and many other universities which would be “of little use in producing employable computer professionals” (Woodhouse 1992), in addition to programming (ALGOL, Pascal, 6800 assembler, PDP-11 assembler, and COBOL), software engineering, computer organization, and operating systems and Information Systems, La Trobe added Systems Analysis and Design (not then really considered to be a proper part of “real”

Computer Science) along with Introduction to Accounting, Management Accounting, Numerical Methods, Operations Research, and Social Psychology.

Types of Computing Courses

The question of whether *Computer Science* was a branch of science or a branch of engineering or whether it was something else entirely unique had been under discussion since the 1950s, and consensus only emerged by the early 1980s that it was a distinct discipline (Gries et al. 1989). *Business Computing*, which some had suggested was “just a watered down version of Computer Science located in an organizational context,” took a little longer to gain disciplinary status. *Business Computing* (or *Information Systems* as it is now called) was seen as “curricula designed primarily to educate people in the efficient and effective application of computer hardware, software, and systems to the solution of business and organizational problems.”

It is useful to consider the relationship between three separate computing course entities during the 1970s that have grown up together to produce the current courses in *Computer Science* and *Information Systems*:

- Academic Computer Science courses taught at most universities
- The Applied Sciences type of Business Computing taught in the CAEs
- Faculty of Business degrees in Business Computing taught in the CAEs

Business Computing to Information Systems

In the 1980s it was typical in the CAEs for somewhat different forms of computing to be taught in Faculties of Business and Applied Science. For instance, at the Bendigo College of Advanced Education (1984):

- *Bachelor of Business (Data Processing)*. This typically consisted of general business subjects including Accounting, Economics, Business Statistics and Business Law, several Business Data Processing subjects, and some electives.
- *Bachelor of Applied Science (Computing)*. This had rather more in common with a typical Computer Science course: Computer Programming, Information Systems, Finite Mathematics, Elementary Calculus, Information Processing Projects, Quantitative Management Techniques, Computing Machines, and several electives.

In the early 1980s, Footscray Institute of Technology updated its *Associate Diploma in Secretarial Practice* to include a substantial computing component: word processing, office automation, use of computer technology, and electronic mail. This brought Business Computing further into the Business Faculty. In 1987 at RMIT, a Department of Business Information Systems was set up. After this time at most CAEs, reference to *Business Computing* changed to *Information Systems*.

In July 1988 a Commonwealth “White Paper” (Dawkins 1988) set out a policy to recommend the abolition of the binary divide between Universities and Colleges of Advanced Education and the merger of the former CAEs either with each other or with existing universities to form new universities.

Around this time, traditional *Business Computing* curricular was beginning to develop into *Information Systems*, and most courses had a core of similar topics which were typically based around subjects related to Systems Analysis and Design, database design, business programming (which at that stage was typically done using third generation such as BASIC, COBOL, or Pascal), and Systems Implementation. Many of these courses at the time also had an introductory computer networking unit which was probably the most technical and close to the discipline of Computer Science. Subjects handling computer architecture were probably well into the realm of Computer Science and were often electives (Tatnall and Burgess 2009).

By the late 1990s and early 2000s, a typical course in *Bachelor of Business (Information Systems)* would contain some combination of the following subjects:

- Core business studies: Accountancy, Business Law, Economics, Marketing, and Management
- Computing studies: Systems Analysis and Design, Database Systems, Programming Languages, Database Management Systems, Networking Technologies, Information Ethics, Business Process Modelling, Information Management, IT Project Management, Systems Implementation, and Application Development

Conclusion

The mission of a university Department of Information Systems is quite clear: it must research, investigate, and teach how businesses, and other organizations, can make the best use of computers and information technology (IT) to further their business and organizational aims (Tatnall 2006). By its very nature, Information Systems (IS) is an applied discipline that is closely related to the use of information technology in business applications. Information Systems, as a discipline in its own right, is seen to be separate from Computer Science in that it concentrates upon the socio-technical aspects surrounding the implementation and use of ICT in organizations rather than the technical side of systems development. This does not mean that the more technical aspects of Computer Science do not have a place in Information Systems as the disciplines do overlap and those boundaries are often blurred. Courses in *Business Computing* in the CAEs did thus not diverge from university *Computer Science*.

Blended Learning

Sawsen Lakhal and Florian Meyer
Département de pédagogie, Université de Sherbrooke, Sherbrooke, QC, Canada

Synonyms

[Hybrid learning](#)

Definition

Over the last two decades, the term *blended learning* has been used more and more frequently in education, military, industry, and corporate sectors, as well as other organizations with training responsibilities (Moskal et al. 2013), and its definition has evolved over time. In fact, in the late 1990s and the beginning of the 2000s, *blended learning* was defined as any combination of technologies, pedagogies, and job tasks. For example, Driscoll (2003) viewed *blended learning* as different possible mixes of (1) web-based technology, (2) pedagogical approaches with or without instructional technology, (3) any form of instructional technology with face-to-face learning, and (4) instructional technology with actual job tasks. Other possible combinations were also added to the concept such as face-to-face learning with online learning, online learning with access to a coach or a teacher, simulations with structured courses, etc. Thus, *blended learning* meant different things to different people. Since 2006, the definition of *blended learning* has converged and stabilized. According to Garrison and Vaughan (2008), blended learning combines face-to-face learning with online learning in a planned, pedagogically valuable manner, to form an integrated instructional approach. As such, it is not a simple addition of online sessions to face-to-face sessions, but it supposes reassessment and reengineering of the entire course, including the use of new instructional strategies. In *blended learning*, teacher and students work together in mixed delivery modes in order to accomplish learning outcomes that are pedagogically supported through teaching, learning, and assessment activities, as appropriate for a given mode, and to offer a meaningful course environment to the students (McGee and Reis 2012). They have to rely strongly on a digital environment specifically structured and organized to support these mixed delivery modes.

Even if the definition of *blended learning* seems to be simple, it can take on different forms along a continuum, with a focus on face-to-face activities complemented with online activities on one end and, on the other end, a focus on online activities complemented by face-to-face activities.

For example, in primary and secondary education, a taxonomy of four models was developed by Staker and Horn (2012) using this notion of continuum: rotation, flex, self-blend model, and enriched virtual model. In higher education, other models exist such as supplemental, replacement, emporium, and buffet (Graham 2013).

Introduction

Improvements in information and communication technology (ICT) have had a significant impact on teaching and learning in education. New opportunities have arisen that were inexistent not more than a decade ago and have resulted in, among other things, a variety of course delivery modes such as web-facilitated face-to-face, blended, and online courses. A course delivery mode refers to decisions about the manner of presenting the content and teaching, learning, and assessment activities designed into the course. These new course delivery modes make it possible to recruit more students and to better accommodate them (Allen et al. 2016). Indeed, for example, online and blended courses meet the demands of students who desire flexible course schedules, like adult students who would not be able to attend face-to-face courses because of family and/or work responsibilities. Also, these various delivery modes give students better access to education especially in large and vast countries such as Canada, Russia, or Australia, where distances can be quite significant between students' homes and educational institutions. Finally, they can significantly decrease educational costs for students and for educational institutions. Students would not need to travel as much to attend face-to-face sessions while benefiting from direct or indirect contact with the teacher and other students. In addition, educational institutions can free up space on campuses as students and teachers no longer have to meet in person within a physical location for each class session.

Allen et al. (2016) placed the course delivery modes mentioned above on a continuum. At one end of the continuum is face-to-face mode, which involves traditional or web-facilitated teaching and learning. Face-to-face mode is called

traditional if there is no use of online ICT within the course. All teaching and learning activities are carried out in writing or orally. Face-to-face mode could also be web-facilitated; in other words, web-based ICT is used to facilitate and support the face-to-face course. In this mode, for example, the teacher could use a learning management system (LMS) or web pages to make the course outline and assignments available to students. At this end of the continuum, the proportion of teaching and learning activities delivered online can vary from 1% to 29%. Many examples of this mode can be found in primary and secondary schools, colleges, and universities. It could either be found in regular classroom contexts where students have multimedia resources to manipulate or at home in order to complete some asynchronous learning activities. These resources include videos, forums, social medias, quizzes, etc. For example, one chemistry teacher implemented a flipped classroom, which is a proper illustration of this specific context (<https://mrprofdechimie.com/classeinverse/>). It could also be used in a special context like regular classrooms with sports or arts concentrations in which some students have to travel every now and then for events related to their specialties and need to complete learning activities outside the classroom while traveling. For example, the Beauce-Etchemin school board offers this kind of online support for their students (<http://coursenligne.csbe.qc.ca/>). It could also be used in schools in small isolated locations that connect with other schools in order to open the doors of their classrooms to other realities. The *École en réseau* network in the province of Québec is emblematic of this context (<https://eer.qc.ca/reseau>). In these three cases, most of the learning activities take place in a synchronous manner, and all the learners are present in the classroom.

At the other end of the continuum is a mode in which most or all of teaching and learning activities are delivered online (80% and more). The Master's degree in secondary education of the Faculty of Education at the University of Sherbrooke is a specific example of this mode. For every course, the students have to carry out online activities either synchronously or

asynchronously on Moodle, Mahara, WebEx, or other platforms, except in one specific course that requires students to meet professors and peers in class for the presentation of their professional portfolio (<https://www.usherbrooke.ca/admission/programme/665/maitrise-en-enseignement-au-secondaire/>).

Finally, in the middle of the continuum is *blended learning*, which combines face-to-face and online modes. According to Allen et al. (2016), blended mode features learning environments in which 30–79% of teaching and learning activities are carried out through web-based ICT. These proportions might change from one institution to another, from one education level to another, from one context to another, and from one author to another.

It is worth noting that some authors emphasize the necessity of reducing face-to-face time of instruction in favor of online activities (Graham 2013), whereas others mention the strength of variation (Staker and Horn 2012). More and more universities adopt this course delivery mode, and many examples can be found online. For example, the University of Ottawa (Canada) offers a large number of courses within this format (<https://tlss.uottawa.ca/site/blended-initiative>). This university clearly defines a blended learning course as “designed such that some in-class time is substituted by equally meaningful online activities” and where many divisions are possible between face-to-face and online hours.

In light of the definition presented previously, “Blended learning should be viewed as a pedagogical approach that combines the effectiveness and socialization opportunities of the classroom with the technologically enhanced active learning possibilities of the online environment, rather than a ratio of delivery modalities. In other words, blended learning should be approached not merely as a temporal construct, but rather as a fundamental redesign of the instructional model with the following characteristics:

- A shift from lecture- to student-centered instruction in which students become active and interactive learners (this shift should

apply to the entire course, including face-to-face contact sessions)

- Increases in interaction between student-instructor, student-student, student-content, and student-outside resources
- Integrated formative and summative assessment mechanisms for students and instructor (Dziuban et al. 2004, p. 3)

Conditions for Success

In order to ensure successful learning within a blended learning course, different conditions for success and recommendations should be considered. Some of these conditions and recommendations apply to the general environment and others more specifically to course design or the course session. The following recommendations were identified from within the literature:

1. Gradually integrate blended learning, especially in education institutions where face-to-face instruction dominated for several years, and be aware of the stages of institutional adoption of blended learning (awareness/exploration, adoption/early implementation, or mature implementation/growth) because consideration of these stages could influence different levels of institutional support.
2. Ensure the availability of sufficient support from the education institution regarding the implementation of this course delivery mode. The implementation of successful blended learning courses requires alignment of institutional, teacher, and student goals.
3. Make sound decisions on the technologies and activities to be selected for use within the blended course. These decisions are taken according to teaching preferences and the technologies available in the education institution, and consider characteristics of the students enrolled in the course, i.e., age, maturity, learning styles and preferences, access to the Internet, ease of use of technologies, socio-economical background, etc.
4. Use the appropriate equipment in order to optimize students' experience within the online component of the course and to ensure students' access to learning activities and course material anytime and anywhere.
5. Test and practice the use of the various technological tools involved in the blended learning course before the beginning of the course. It is important for teachers to prepare in advance and to have some ease and facility using these tools. It seems to be even more important for teachers to reach a certain level of technological pedagogical knowledge to ensure good implementation and usage of these tools. It is also recommended to invite students to participate in training sessions for the technological tools being considered for use.
6. Test the functionalities of the communication system, the quality of the network connection, or the platform used in the blended course before the beginning of the course. These technologies should be performant in terms of functionality, robustness, and reliability.
7. Integrate different teaching and learning strategies in order to meet different learning styles. Moreover, blended learning is not the addition of online teaching and learning methods to face-to-face ones but requires new methods of teaching, learning, and content development and can rely on different forms of educational relationships and pedagogical control. In this regard, the redesign of a course would require 3–6 months based on a structured instructional design method. To be able to enjoy the benefits of blended learning, other possible blends should also be considered in the design.
8. Use asynchronous communication tools in the online component of the course to keep students engaged in the course, such as discussion forums or other social media.
9. Rethink the way that teacher and student roles are conceived. In blended learning, teaching and learning strategies should be more student centered. Teachers should enhance students' participation in their learning and support interactions in face-to-face and online sessions. If a class is considered as a community of inquiry, blended learning can create and sustain productive conditions that will benefit everyone engaged in positive learning experiences.

Advantages

Blended learning has been reported to be preferred by students to online courses and face-to-face courses. For example, the results of a study by Owston et al. (2013) conducted among university students revealed that blended course delivery mode was preferred to traditional face-to-face mode and online mode by high achiever students ($n=577$). Moreover, this mode is perceived as a “best of both worlds” approach as compared to online courses, and it may have a higher acceptance level and a higher perceived value (closer to face-to-face learning) than online courses (Allen et al. 2016).

It provides students with greater educational access, especially for those who live far away from campuses and for those who have a very demanding schedule for work or family responsibilities that make it difficult for them to attend face-to-face sessions every week.

It reduces educational expenses, and it may represent a solution for educational institutions with limited classroom space. It has been reported to increase student enrollment and to reduce instruction costs as the classroom resources are used more efficiently with a reduction of seat time.

It enriches the teaching and learning environment, as artifacts from face-to-face learning activities (such as audio/video recordings) may be used as learning objects, and artifacts from online learning activities (such as forums) may be used as learning objects in face-to-face activities. As such, blended learning offers teachers and students the “best” educational experience as compared to the traditional face-to-face or online learning.

It has been reported to be more effective and educationally beneficial for students as compared to face-to-face and online learning. Moreover, results of recent meta-analyses reveal that knowledge acquisition and achievement outcomes were higher in blended learning environments than those in face-to-face and online learning environments (Liu et al. 2016). Blended learning allows teachers to track students’ involvement and progress much better than in a

face-to-face learning environment. It also permits students to review digital materials as often as needed and at their own pace, which likely enhances learning performance. Moreover, as compared to online learning, students are less likely to experience feelings of isolation, which could in turn assist in maintaining interest in the subject matter (Liu et al. 2016).

Challenges

Lack of institutional recognition for the amount of effort needed to be put into the design of a blended course. This lack of support may leave teachers feeling unsupported in their efforts to innovate. Indeed, the blended learning course design demands much more preparation than courses in a single mode, i.e., face-to-face or online, such as setting up the rooms (both physical and virtual classes) and planning meaningful interactions and collaboration between students. These interactions and collaborations do not occur spontaneously and have to be well planned.

Students’ level of technological skills could be a challenge in this kind of course. If some students lack technological skills, teachers may focus on these students and spend their time troubleshooting students’ technical problems. The technologies used in these courses need to be easy to use, recent, and appropriate in order to motivate students to use them and to offer to them a meaningful learning experience.

Access to the online component of the course could represent an important challenge for students. The high cost of connectivity and technology issues may be important barriers for students in accessing the online component of the course and may compromise their learning. For example, cooperative tasks may be difficult to carry out in the virtual environment, and additional efforts may be required to foster group communicative interactions in the instructional process.

Lack of support and training for teachers. Even if blended learning can represent a significant reduction of costs, it still requires an important investment so that teacher’s competencies are developed to their fullest and benefit the

quality of teaching and learning. If the educational institutions do not support and do not offer sufficient training to their teachers, it might be difficult to create and sustain the productive conditions that could benefit everyone.

Other Terms and Approaches

The definition of blended learning, as explained earlier, has evolved throughout time, and some alternative terms are still present within the literature. Here are some of these terms. They can be easily linked to blended learning.

Hybrid learning is often used in the literature as a synonym of blended learning. However, according to McGee and Reis (2012), “hybrid suggests that one mode is unused, while the other is used” (p. 8). This means that the term hybrid refers to situations where there is a clear distinction between face-to-face activities and online activities, whereas blended suggests that there is no clear distinction between the face-to-face and online activities and no perceivable moments when modes shift.

HyFlex is a six-letter word that is a *portemanteau* of the terms *Hybrid* and *Flexible*. The Hybrid-Flexible (HyFlex) instructional model is a course design model that combines *Hybrid* learning in a *Flexible* way, such that students can either attend face-to-face class sessions, participate online, or do both according to their needs and availability.

Multiaccess learning refers to a “choice learning” mode where students control how they wish to participate in their course, with a distant small group via video conference or a face-to-face on campus group, individually by means of desktop web conferencing, or online asynchronously, etc.

Synchromodal learning refers to classes in which online students and face-to-face students interact with each other during shared synchronous sessions. As such, some students experience the course in a mediated format and others in an unmediated one. The delivery pattern in this course format includes lectures, linked classrooms, shared portals, personal portals, and small groups.

Blended synchronous learning is defined as mixing both asynchronous and synchronous online learning, to which face-to-face learning opportunities are added. It is about learning and teaching where distant students participate in face-to-face class sessions by means of video conferencing and web conferencing.

Blended online learning refers to fully online learning with synchronous and asynchronous teaching and learning activities.

Flipped classroom can be considered as a blended learning format that combines both face-to-face mode and asynchronous virtual mode. In a flipped classroom, asynchronous virtual activities are focused on the autonomous appropriation of mediated content or annotated preparatory readings, whereas face-to-face activities in the classroom are characterized by the valorization of active learning methods. Staker and Horn (2012) consider flipped classroom to be one of the rotation models in their blended learning taxonomy.

Conclusion

In conclusion, blended learning is an integrated pedagogical approach which combines face-to-face learning activities and online learning activities. It implies a reassessment and reengineering of every aspect of traditional courses and face-to-face class sessions. It requires teachers and trainers to redefine their instructional strategies and activities in order to support collaborative and active learning and to ensure that learning outcomes are reached in a meaningful context and adapted to the different modes of delivery.

This entry defined what is meant by *blended learning* and presented different conditions of success and recommendations to ensure successful learning within this course delivery mode. It also highlighted the five main advantages of using blended learning, but also explained that achieving a successful blended learning environment requires overcoming important challenges that every school, college, or university’s stakeholders, administrators, and teachers should seriously take into account: institutional

recognition for the amount of effort to be put into the design of a blended course, students and teachers' level of technological skills, access to the online component of the course, and quality support and training for teachers. Finally, other terms and related approach to blended learning were presented with the aim of providing a more complete portrait of the phenomenon.

Background

This entry explores how educational technologies are being used and can be used to develop what have been referred to as “new ways of teaching and learning.” These new ways, adopting a variety of forms of educational technologies, have variously been termed “e-learning,” “online learning,” and “blended learning.” In this entry, these “new ways” are examined, and key elements of technology, management, and pedagogy that must be focused on if future provision is to support both educational intentions and learner expectations are argued.

This entry will consider the question framed by its title – Blending Learning Provision for Higher Education: Integrating “New Ways” of Teaching and Learning. This concern, common to many institutions of higher education (HE) worldwide, will be examined through a policy and practice analysis perspective, taking existing literature in the field as a conceptual and contextual basis, considering examples of blended learning practices, identifying key features that support effective outcomes, and subsequently considering these in terms of implications for wider global practices where massification of education is being considered.

Focus and Purpose

This entry will critically review literature that has shaped and informed developments and practices related to “new ways of learning and teaching.” It will draw on the author’s experience and practices with online programs, and place these within a wider context, where increasing participation and massification are of fundamental concern.

Initially, definitions and uses of the terms e-learning, online learning, and blended learning will be considered, so that their use within this entry (and perhaps more widely) can be understood from the perspective of their delineation, since the different conceptions that underpin these terms have often been blurred or, indeed in some cases, the terms have been used synonymously.

E-learning is defined as, according to the outcomes of the study of Sangrà et al. (2012, p. n.p): “an approach to teaching and learning, representing all or part of the educational model applied, that is based on the use of electronic media and devices as tools for improving access to training, communication and interaction and that facilitates the adoption of new ways of understanding and developing learning.” These authors have elicited, using an appropriate methodological approach, what they consider to be an inclusive definition. It is clear that their inclusive e-learning definition, however, refers only to elements of programs or courses that use electronic media and tools. Consequently, e-learning is concerned fundamentally with forms of provision, rather than being led by concerns with teaching or learning.

Online learning, according to Watson et al. (2004, p. 95), is defined as: “education in which instruction and content are delivered primarily via the Internet.” Online learning is also, therefore, a term concerned with provision but focusing on provision where the Internet is primarily involved. Again, provision is fundamental here, rather than the concept being driven by specific approaches to teaching or learning.

Blended learning, according to Staker and Horn (2012, p. 3), is: “a formal education program in which a student learns at least in part through

online delivery of content and instruction with some element of student control over time, place, path, and/or pace and at least in part at a supervised brick-and-mortar location away from home.” Blended learning according to this definition is, therefore, not only concerned with provision but also with the ways that technologically supported and non-technologically supported elements of education might interplay or be integrated. It is this form of approach that, together with associated teaching and learning concerns, will be the focus of this entry.

Introduction: Parallel Research Concerns

Many HE institutions worldwide are investing in technologies to support teaching and learning, driven also by their need for engagement with wider and increased populations of students. In the latest Universities and Colleges Information Systems Association (UCISA) survey (2014), one of a series of such surveys and reports which have gathered evidence from HE institutions across the UK, all 94 institutions that responded in that survey reported using a virtual learning environment (VLE). This is recognized as a key technological tool (or rather a set of tools, which might include a bank of learning resources and a range of communication channels such as messaging, discussion forums and chat rooms, online assignment management, and online communities) to support blended learning provision, as it enables participation in learning activities that can happen at home or outside classrooms but further allows the integration of those activities and outcomes with those from within classrooms. In the UCISA (2014) survey, the most commonly, centrally supported technologies (which could well be linked to the VLE as integrated facilities) were plagiarism prevention and detection software and e-submission tools. E-portfolio, blog and e-assessment tools, and personal response systems (PRS) were also reported to be supported widely across HE institutions. Lecture capture and media streaming solutions were the emerging technologies that arose most often since the previous survey had been reported. It is clear that all

of these tools can be considered as those fundamental to support of different aspects of blended learning provision.

HE institutions are being driven to develop blended learning provision for one or more different reasons. Bonk et al. (2006, p. 560) identified from their survey a number of significant drivers, as well as a number of trends arising at that time, as HE lecturers considered developing and adopting blended learning practices: “[the rise in access to and uses of] mobile blended learning; [enhancements through] greater visualization, individualization, and hands-on learning; [greater control through] self-determined blended learning; increased connectedness, community, and collaboration; increased authenticity and on-demand learning; linking work and learning; changed calendaring [becomes increasingly easy]; blended learning course designations [are increasingly made available as options]; changed instructor roles [become more recognised]; the emergence of blended learning specialists [increases over time].” Ten years later, it is clear that these drivers and trends are still identifiable – and the external policy and social concerns are, if anything, more pressing and prevalent.

Such pressing policy and social needs have just as much a presence in India as they have in many other countries. With a plan to increase overall gross enrolment ratio (GER) in HE in India to 50% by 2030, this is calculated to lead to an estimated additional capacity need (let alone parallel, additional lecturer support need) for 40 million students in the sector (EY 2014). In this context, it is clear that the Government of India wishes to consider how to effectively develop online and blended courses and programs to increase and support the consequent, necessary HE access. As stated in a press release from the Ministry of Human Resource Development (2015): “Under National Mission on Education through Information and Communication Technology (NMEICT) scheme, 403 universities have been provided One Gbps connectivity and 21,766 colleges, including affiliated colleges through 20 nodes each of 512 Kbps broadband connectivity, so far. The Government does not

conduct online courses itself, however, it facilitates the educational institutes to make and offer online courses in various disciplines under NMEICT scheme.” While this press release states the development in terms of online courses, evidence about different forms of blended learning provision, with online learning lying at the more “online only” end of a spectrum, suggests that different forms, involving different blends of online and on-site provision, are worthy of consideration; different blends may match and suit different subject needs, as well as local and individual learner circumstances (see, e.g., Staker and Horn 2012, for a discussion of different options within the compulsory school sector).

Research has explored a range of perspectives within the field of blended learning. However, blended learning provision has certainly not been the sole concern of research looking at the entirety of educational development over the past few decades (the time since the Internet brought forward opportunities for high-speed and opportunistic communication between locations and individuals). Indeed, over the past 20 or more years, there have been a number of parallel streams of research in education and its future development. One of these streams has focused on approaches using technology-enhanced learning, while another has focused much more on learning and learning theories per se. At the same time, there has been a convergence, arising from concerns that research into technology-enhanced learning environments and situations should be considered in the context of emerging associated learning theories. Hence, there has been an emergence of research focused on fields such as “computer-supported collaborative learning” (see Stahl et al. 2006) and “networked learning” (see Dirckinck-Holmfeld et al. 2009), for example. In these cases, there is clearly a relationship argued between the provisions of education through uses of technologies (albeit perhaps in specific forms) and learning arising. The relationship between practice and research, and the limitations that a greater focus of research on technology might have produced, has recently been raised critically in these fields (e.g., Oliver

2011; Selwyn 2010). However, it is clear that practice using blended learning provision or approaches has been developed over the past few decades and indeed has been recognized to have been successful when measured through appropriate learning outcomes (see, e.g., Passey 2014). However, when outcomes have been identified as being successful, the roles of teachers have been recognized as being vitally important (see, e.g., Tamim et al. 2011). In this entry, it is argued that the roles of program and course aims and intentions are just as vital, and indeed those aims and intentions may themselves form the bases of interactions between the practice and theories that can underpin these programs or courses and subsequently lead to outcomes of recognized success.

“New Ways” of Teaching and Learning

Some authors and institutions might argue (and some certainly state) that there are “new ways of learning” (see, e.g., NTU Education 2012). But it is also possible to argue against these forms of assertion, especially since “new ways of learning” (where learning is concerned with the internal processes that the individual adopts) are difficult to identify. For example, while computer-supported collaborative learning has been identified as a field worthy of specific research activity, collaboration, as a way of learning, is not a “new feature” or a “new way.” The medium through which it occurs (communication technologies) is new (relatively speaking), but does this mean that the learning *per se* is “new?” Do learners using a technological environment, where collaboration is the focus, not also share their ideas, amend and modify, produce outcomes that integrate their ideas together, and end with an outcome or product that addresses a problem where their individual contributions are difficult to identify? The “new” element here appears to be the medium and the context in which it is occurring, rather than the learning.

If ideas of “new” ways of learning are to be accepted, then it is also necessary to recognize

“old” ways too. A “very old” way of learning, the Socratic method (described by, e.g., Gose 2009), is in some respects what some others might regard as “new,” since it involves learning through social interaction and questioning, rather than learning through a solitary individual focus where the learner is the recipient, taking on board what the teacher delivers. Trying to define “new” and “old” ways of learning is, therefore, potentially problematic. When learning arising from using new technologies is reviewed against a wide framework of learning elements (Passey 2014), it is not shown that “new ways” emerge. On the other hand, Passig (2007) has identified melioration as an additional thinking skill that he argues should be added to Bloom’s taxonomy (1956). But such identification is not common and is contested.

If broader learning approaches are considered, rather than more specific learning elements, then there are a number of “new” ways that have been claimed over the past 60 or so years. Some of the “new” ways that have been proposed are problem-based learning (PBL), described by Barrows (1996); authentic learning (AL) described by Donovan et al. (1999); dialogic learning (DL) described by Alexander (2008); situated learning (SL) described by Lave and Wenger (1991); technology-enhanced learning (TEL) described by Kirkwood and Price (2014); networked learning (NL) described by Dirckinck-Holmfeld et al. (2009); computer-supported collaborative learning (CSCL) described by Stahl et al. (2006); and mobile learning (ML) described by Crompton (2013).

When this list is considered, there is little doubt that the possibilities technologies afford have certainly been enhanced, not only has such enhancement arisen in terms of when learning can happen (e.g., as access can happen at any time if resources are online, through ML), and where (e.g., as access requires technological rather than physical access, through NL), but also how (e.g., as interactions can occur with a potentially wider variety of participants, at a distance, synchronously or asynchronously, depending on circumstances, through CSCL).

Shifts in Teaching and Learning Processes

But there is a need for some clarity and detail when considering how technologies can be integrated into teaching and pedagogical practices. When teachers deploy technologies to support pedagogies, the forms of provision mean that teachers need to consider the practices they can use to gain from the technological affordances available. Mishra and Koehler (2006) identified three areas of knowledge that teachers need as starting points (technological, pedagogical, and content knowledge). But these authors also argued that integration of technologies into teaching and pedagogy requires the development of forms of knowledge that bring these elements together, so that an understanding of the ways each one relates to the other can be applied within curriculum situations. However, it can be argued that considering pedagogy through a single educator mode (the teacher) is unlikely to provide sufficient breadth of ideas of how to undertake the width of practices that are opened up. Pedagogical knowledge will be affected by the mode that an educator might take (e.g., whether that mode is a teacher, focusing more on delivery of content and subject, or a tutor, focusing more on working with learners, or a guide, focusing more on supporting learners if and when they require assistance). The differences that these modes make to practice are not always easily delineated in some of the models associated with social constructivist approaches, which can tend to rely more on a tutor or guide mode. Models developed and used in this field of research, such as Laurillard's Conversational Framework (Laurillard 2002) or Mazur's Flipped Classroom Model (Mazur 2015), therefore, need to be considered further in the context of teacher or pedagogic mode.

Models and frameworks such as those of Laurillard and Mazur reflect on outcomes of approaches used to address more general demands worldwide for increased levels of HE, as well as increased opportunities through diversity of opportunities, not just in terms of subject and content, but also in terms of pedagogical

approach. While the trends to shift pedagogies are to move toward more situated, discursive, and socially constructive approaches, the trends to shift HE access are to move to higher levels of access, with increased learner numbers being supported by pedagogies that are focused on high output. Hence, perhaps, the support gained for massive open online courses (MOOCs) in recent years, due to access they provide being wide and high (although retention and outcome in terms of learning is not always reported to be strongly identified or necessarily high). However, researchers have argued that such levels of retention and outcomes should be expected (Koller et al. 2013).

The trend that is seen here is concerned with pedagogical shifts (that are also linked to necessary future skills): a shift away from transmission pedagogy; a greater balance between transmission and participative pedagogies; more of a focus on learner-centered approaches; concepts of social constructivism being integrated to greater extents; learner responsibilities being shifted; forms of engagement and activity widening; more individual responses and discussion being introduced; greater emphasis on tutoring, guidance, and facilitation; and a greater range of tools being introduced and used.

Teaching for the future needs to consider how ongoing change, where technological tools are introduced, can harness and develop practices in supporting a balance between transmission and participative pedagogies, finding ways to enable students to develop and share ideas and their approaches to study (e.g., discussed by Murphy and Wolfenden 2013); a focus on student-centered approaches, perhaps considering what is being called the "flipped classroom" model, where video or audio is used prior to classroom sessions, which are followed up by in-class discussion and reflection (e.g., discussed by Mazur 2015); concepts of social constructivism being integrated to greater extents, allowing for students to discuss and question through various formats, in groups in class, via a VLE or even via social media; student responsibilities being shifted, and how learners will gain a greater autonomy for learning through wider self-regulation (and perhaps this latter

competence being “taught” or “tutored”); forms of engagement and activity widening, being able to see and experience a width of activities that others are undertaking, through video case studies, for example;; greater emphasis on tutoring, guidance, and facilitation, but without losing the necessity for direct teaching where appropriate; and a greater range of tools that are being introduced and used, and how to identify the affordances for pedagogy and content that these bring.

What Is New: The Management of Learning

What is clear is that the management of learning and the management of learning activities can be developed and shifted using new technologies. The management of learning and learning activities means that provision can be blended, teaching can be blended, but learning can remain focused on identified learning aims and objectives, essential skills, and outcomes. Provision (a proportion at least) might as well occur at a distance, and in different forms, which should involve a range of activities, perhaps discussion, review, or use of online simulations, for example, covering asynchronous online activities or synchronous video chat.

The management of blended learning is seen to offer benefits for learners and teachers. A report of findings in the State of Victoria in Australia (Department of Education and Early Childhood Development 2012, p. 22) stated a wide range of benefits that can also apply to students in HE: “inclusion of more differentiated/personalised instruction; increased access to resources, experts and learning opportunities; more authentic and student driven tasks being incorporated into the curriculum; higher student engagement; greater opportunities for collaboration (especially beyond the classroom and involving the wider school community); exposure to a wide range of Web 2.0 technologies and acquisition of contemporary literacy skills; better access to infrastructure and, anytime, anywhere learning.”

Online access allows a greater emphasis on mentoring and guidance, with learners taking

greater control and responsibility for their learning. Studies have shown that using technologies can support teachers shifting their focus away from lower-order thinking and skills toward higher-order thinking and skills (Toyoda 2015). For example, use of simulations can allow a greater focus on analysis. However, at the same time, there is a need for learners to have high levels of self-regulation with regard to their engagement and learning. Interestingly, studies have shown that, when learners who have been involved in school systems where regulation is highly focused on school regulation rather than self-regulation, dependency on school regulation can persist in learners (Raahem and Wankowski 1981). It seems that a focus on supporting self-regulation (a key characteristic of expert learners or megacognition, Passey 2014) should be a major concern for future educational systems, whether these systems adopt on-site, off-site, or blended provision models.

Modes and Globalization

Globalization, and the opportunity for all young people and learners to have access to education, places huge demands upon educational systems and practices. At this time, it is difficult to see that there are sufficient numbers of teachers available to support the number of students who currently wish to learn; yet this figure will continue to increase and not decrease in the future. Whether greater opportunities through using technologies to support blended provision, blended teaching, and focused learning can be achieved is not a new question. But what is clear is that current and future teachers need to be prepared for modes that go beyond on-site provision; the practices of tutoring, facilitating, and guiding require different qualities and concerns. The forms of teacher support provided by School of the Air in Australia, for example, or by the UK Open University undergraduate or graduate programs rely on limited or particular teaching support, with far greater emphasis placed on self-regulated learning, where the learner takes more responsibility for lower-order knowledge acquisition, understanding, and comprehension, while

online activities and interactions support the need for more higher-order skills such as application, analysis, synthesis, and evaluation. Teacher opportunity and location, as well as learner opportunity and location, also need to be considered in this context. CNED (the National Centre for Distance Education), an arm of the Ministry of National Education, Higher Education, and Research in France, is a large organization, comprising some 100 employees in the central management team and some 2,200 teachers (most of these undertaking marking of completed work rather than interacting online). The number of employees is some 3,500 in total (some 1,200 employees developing online resources). CNED makes available about 500 courses, with some 3,000 modules, for students across the age range, from primary to secondary, vocational, higher, and professional education (CNED 2014). The organization has supported the educational needs of those not able to attend educational institutions for whatever reason (physical, mental, or emotional). Teachers who are not able to physically attend schools are employed by CNED, enabling an additional pool of expertise to be accessible to learners.

In the context of India, such opportunities are worthy of some consideration. The UNESCO e-Atlas of Teachers (n.d.) estimates that India will need to recruit three million teachers by 2030 due to the demand arising for new posts and due to current and future attrition. The UNESCO Institute of Statistics (2016) states that there are currently 181,872 HE students from India studying abroad; most of these are in the USA (97,613), Australia (95,562), and the UK (19,604). Taken together, it is clear that the demand for education will increase, yet it is unlikely that the demand can be sustained economically in the same way that it happens currently. “New ways of teaching and learning” are therefore likely to be required to manage this emerging situation. Exploring current patterns of managing blending learning that are recognized as being effective is one way to develop possible models that might support the necessary massification of education.

Examples of Blending Learning Approaches in HE in Lancaster University

The Department of Educational Research at Lancaster University has developed blending learning approaches over many years. It offers four different online programs for doctoral study. There are few such programs worldwide at this level, and different ways of blending provision have been considered and adopted with these programs. There are modular assessed elements, followed by a longer in-depth study that leads to a thesis, which is assessed by an academic panel (usually an internal and an external examiner). The residential provision in these programs (to support social as well as intellectual interaction) is blended in different ways: in one program there are a number of regular weeklong residentials; in another program there are 1-week residentials in each of the first 2 years; and in the other two programs, the provision is entirely online (Educational Research Lancaster University 2016).

The example focused on specifically is the e-Research and technology-enhanced learning doctoral program. Although a number of tutors support this program, there is very little focus on teaching per se. Most of the focus is on tutoring, facilitation, and guidance. Learners work through activities, reading key literature, perhaps summarizing, discussing, or drawing out key points or comparisons with other literature. In a range of activities, they make their individual findings accessible to other learners within an annual cohort and to the tutor, who can pick up on any specific points, facilitate discussion by leading on pertinent or related points, and guide on key principles that are emerging. The learner is supported as a self-regulated learner, with a focus on authentic learning (encouraging students to reflect on and undertake studies within their own contexts which can inform their own practice) and problem-based learning (encouraging them to identify key issues and challenges that they face and to use research approaches to consider possible ways to examine these problems).

Blending Learning Provision for Higher Education, Integrating “New Ways” of Teaching and Learning, Table 1 Technology resource categories and examples of technologies supporting “new” ways of learning

Digital technology resource category	Supporting “new” ways of learning	Technology examples
Topic-specific resources and software	PBL, AL	Specific online texts and literature Specific online videos and activities Pointers to online resources in other repositories
Curriculum-wide learner-centered software	PBL	Moodle platform for drawing together all key interactions Discussion fora
Curriculum-wide tutor-centered software	PBL, AL	Access to tutor resources is available to all students Tutor-prepared video clips Online assignment upload Online feedback
Online learner support	PBL	Tutor online summaries Tutor-highlighted resources and individual as well as group feedback

To support the focus on these “new” forms of learning, technologies are used in specific ways (which are exemplified, but not exhaustively, in Table 1).

Using this environment, there is a clear need for learners to be self-regulated and to develop self-regulation (discussed by, e.g., Zimmerman 1986) and the need for them to have access to resources and to ways to handle their identity and agency in this context. So, while there is a strong argument for considering these “new” ways of learning, there are factors that need to be considered in parallel, if efforts are to be successful.

Roles of Teachers and Students

Teaching in classrooms is often blended, with different modes deployed at different times (e.g., a teacher mode is used when some specific topic content is covered, a tutor mode is used when working with a small group focused on a specific activity, a facilitator mode is used when monitoring project-based activities, or a guide mode is used when taking a group around an external site such as a museum or castle). Choosing pedagogical practices associated with these four educator modes is a key element of the teaching armory accessible to the educator. An educator might

deploy these in different contexts; Table 2 provides an illustration of possible matches between these modes and different types of learner interaction that might be involved (these types of interaction being taken from Twining and McCormick 1999).

It is clear from Table 2 that if all types of learner interaction are deemed useful, and are to be accessible to learners, then educators need to adopt a range of different educator modes. How this can be done when using different (and online) technologies becomes a key question when blending learning provision.

Curriculum Design Implications

If the focus of blended provision is to support both effective self-regulation of learners and effective teaching, then the types of interaction and modes of interaction in Table 2 need to be considered in terms of the aims and intentions of programs as well as modules or activities. Where do the fundamental learning needs of a program, module, or activity lie, if online teaching and support is something that will be affected by blended provision but the overall strengths of interactions need to remain?

From Table 2, reducing the elements that are limited by the blended provision (the “teaching” column), and enhancing the elements that can be highlighted by the same provision, a suggested (perhaps ideal) pattern is exemplified in Table 3.

Using the elements in Table 3 as a design model, a program or module would then rely on involvement of the highlighted key factors. Experience in the program run at Lancaster University, and research outcomes from studies focusing on implementing blended learning in various sectors of education (e.g., Department of Education and Early Childhood Development 2012; van Merriënboer and Kirschner 2012) indicate that certain of these factors are relied upon heavily or focused as priorities (related to key aims and objectives of programs, modules, or activities). In terms of influential and important factors, these are:

- Evaluating learners’ responses through tutoring, facilitating, and guiding. Online interactions and responses allow educators to explore and analyze learner responses carefully, considering the strengths of each learner, the gaps or misconceptions in their understandings that might exist, and the ways that the

learner is approaching their learning. This allows educators to accommodate diversity in learning approaches, evaluating forms of interaction that might support individuals and groups most effectively.

- Discussion through tutoring, facilitating, and guiding. Educators might rely upon learners working in groups, initiating discussion, and expecting learners to participate. This allows learners to gain from the experience of others and to be involved in sharing their views and ideas, exposing and developing their understandings, and arguing their positions and findings.
- Scaffolding through tutoring, facilitating, and guiding. Educators can scaffold carefully the activities through each module of a program. Educators might identify key readings, ask learners to perhaps summarize these in groups, discuss key points, highlight weaknesses and strengths of aspects of those readings, and consider how they would apply these within their own contexts. Educators can support research and proposal writing and scaffold approaches to research studies.

- Questioning through tutoring, facilitating, and guiding. Educators can ask learners to focus on questioning, critiquing, and highlighting assumptions, rather than stating without substantiation. Educators can be concerned with criticality, supporting learning that arises through problem-solving based on questioning.
- Summarizing through tutoring and guiding. Educators can ask learners to highlight key points and to summarize and to present précises, for example. Educators can facilitate conceptualization, asking learners to consider, adopt, or develop theoretical frameworks and models and how they will relate these to their own studies.
- Initiating and guiding exploration through tutoring, facilitating, and guiding. Educators can initiate and guide exploration, rather than teaching them directly. Educators can expect to shadow learners, offering comment and support along the way, rather than teaching discrete elements and then expecting learners to apply these randomly.
- Speculation through tutoring and facilitating. Educators can expect learners to think about content and concepts and to speculate, rather than to make assumptions. Educators encourage learners to think about options and possibilities and to explore limitations and future potential, rather than accepting what exists without question.

In blending learning provision, there is a need to be mindful of implications, for quality, accreditation, and access. While some might hold concerns about these practices and the implications for quality, accreditation, and access, the reality nonetheless appears to lie with how blended provision is handled, rather than blended provision being unsuitable. Having said this, blended provision clearly needs to accommodate specific subject and topic needs. Within my own subject area, education, it is perfectly feasible for blended provision to support any topics that might be identified. Within engineering, however, there could be greater limitations, where access to specific equipment might be needed. The blend is likely, therefore, to need to vary across subjects and across topics.

Quality of provision needs to be maintained by the management of the provision, the management of the teaching, and the management of the learning. Accreditation is an important element within this concern for quality. Criteria need to be clear, and the same standards for accreditation need to apply when programs are blended or totally on-site. Self-regulation needs to be built into this; learners need to acquire understandings of the standards required and the criteria that will be applied. Authentic learning and problem-based learning relate to this also: that the standards and criteria apply to authentic situations and problems in the individual's context. Once these are in place, then access becomes a reality. Access does not mean access to provision; it means access to the standards and criteria to judge the study that is undertaken. The location and the circumstances become less important when this is the case.

Possibilities for Remote Areas and Widely Distributed Communities

Blended programs at Lancaster University and elsewhere have shown that it is possible to involve and support learners who are remote and who would otherwise not be able to participate. The Educational Research Lancaster University blended programs support part-time doctoral studies with students who are located worldwide (e.g., in the Philippines, in Germany, in Namibia, in Oman, in Canada) and for those who are working full-time, who could not possibly attend a doctoral program on-site in England. They are enabled to focus on their work through their studies (a focus on authentic learning) and to focus on addressing research questions from their fields of work (a focus on problem-based learning).

Conclusions

There is already a rich literature that relates to the development of blended learning. However, the use of the term blended learning hides key factors that need to be considered when developing practices that bring on-site and off-site interactions

into an orchestrated whole. In essence, blended learning is only one of those factors; blended provision, blended learning, and blended teaching are key elements, and perhaps “blending learning provision” is a better way to consider the underpinning concepts.

The analysis of literature and practice presented here suggests that those developing blending learning provision should consider a number of key elements (not necessarily always in the order presented here, as context and focus may affect this order):

- Consider at a program and module level which elements must be undertaken on site, what time needs to be devoted to these, and where in the overall time plan such on-site activities should be located.
- For other elements, identify the learning aims and objectives and how these relate to “new” ways of learning – problem-based learning (PBL), authentic learning (AL), dialogic learning (DL), situated learning (SL), technology-enhanced learning (TEL), networked learning (NL), computer-supported collaborative learning (CSCL), or mobile learning (ML), for example.
- Consider what forms of learning activities can be used to enable the aims and objectives to be met, using “new” approaches to learning, based on a selection of appropriate interactions – instruction, explanation/illustration, direction, demonstration, discussion, scaffolding, questioning, speculation, consolidation, summarizing, initiating/guiding exploration, or evaluating learners’ responses.
- Consider the educator mode or modes that will support these selected activities and learner interactions – teacher, tutor, facilitator, or guide.
- Select the technologies that will support or fulfil these educator-supported activities and interactions – topic-specific resources and software, curriculum-wide learner-centered software, curriculum-wide tutor-centered software, or online learner support.

Blending learning provision will continue to develop as new technologies emerge, practices are implemented, and research identifies the

outcomes of those practices. Interest from universities worldwide in exploring and developing online doctoral research is evidenced from presentations on this topic at conferences and seminars, for example, a presentation at the 9th International Congress on Innovation in Education, 22 to 23 October 2015, Veracruz, Mexico; a presentation at the NEUPA and the British Council “International Seminar on Teaching-Learning and New Technologies in Higher Education,” 25–26 February 2016, New Delhi, India; and a presentation at the 13th Annual Conference on Research and Innovation in Distance Education and eLearning, London, UK. Research has an important set of roles to play in the future, not least to disseminate outcomes to and to support those who will need to shape the current and future, whether they are policymakers, practitioners, or other researchers. How effectively this is done may ultimately shape the value of endeavors for future learners.

Children with autism; Cross-cultural collaborations; HCI4D; Underserved communities

Introduction

Emerging technologies, such as affordable smartphones with 4G access, broadband Internet, and interactive interfaces employing gestures or speech, are revolutionizing the ways we access information, learn new skills, and interact with the world around us. However, developing world

communities – who stand to benefit from such technologies – were, until recently, largely neglected. Interactive technologies can provide a means to overcome social and literacy barriers toward information access. For instance, children with developmental disabilities can use hand gestures to collaborate with a typically developed peer, while rural farmers can use an interactive voice system to gain seasonal agricultural information. When introduced in public spaces, such as schools or community health centers, technology not only provides individual learning solutions and access to information but also encourages and enhances social collaboration and group learning. This potentially brings an overall improvement in people's quality of life, especially to the most vulnerable of these communities, such as rural women and men and children with special needs. Understanding these important user groups and designing for their needs requires a multidisciplinary and multicultural approach toward technology, an approach taken by researchers and designer working with the purview of Information and Communication Technologies for Development (ICT4D) (Heeks 2008) and Human-Computer Interaction for Development (HCI4D).

This chapter details ongoing research that is a collaboration with multiple partners across Finland and India, from both the industry and academia. The research focuses on designing, developing, deploying, and evaluating novel interaction techniques for education (Kallioniemi et al. 2015a, b; Pihkala-Posti et al. 2013, 2014; Sharma et al. 2016a, b, 2018, 2019), healthcare (Sharma et al. 2014), and agriculture (Kallioniemi et al. 2012; Ruohonen et al. 2012, 2013a, b, c; Srivastava et al. 2012) for underserved communities in India. With multinational and multidisciplinary teams across the world, this combined expertise focuses on multimodal interaction with devices, environments, and people to address many future challenges. In education, interactive gesture-based learning applications for children with autism were developed. An embodied navigational game for cross-cultural collaborations for underprivileged

children, who have limited access to technology, was also explored. In healthcare, the use of an interactive gesture-based information system for rural Assamese women was studied. In agriculture, a voice-based mobile agricultural information system for farmers in Karnataka was designed and deployed. These applications are collaborative efforts with Finnish and Indian partners: in Finland with different research groups at the University of Tampere, CIRCOMI and TAUCHI, and with Plural for CityCompass and in India with IBM Research and well-established Indian universities – Indian Institute of Technology in Guwahati, Assam, and University of Agricultural Sciences in Dharwad, Karnataka. In education, collaboration with local non-governmental organizations (NGOs) that cater to children with special needs and children from urban slums was further established. All applications strive to create meaningful user experiences and increase social impact, in addition to increasing technology access and utilization. In this chapter, the key findings from the work carried out in India on education, healthcare, and agriculture are discussed.

A Novel Approach to the Work

The work in India follows a collaborative and ethnographic approach, where researchers spend considerable time in the actual environment and with the different stakeholders. This starts with a user-centered design in which one or two members of the research team interview different stakeholders, for example, teachers, therapists, parents, and students in schools, to understand the challenges toward information access and learning. Together, the problem statement and research hypothesis are defined, and potential design solutions with regard to the type of technology available (mobile phones, laptops, or computers) and most suitable mode of interaction (full-body gestures, speech, or traditional mouse-based interaction) are identified. Then, one or more working prototypes or applications are developed and iteratively improved throughout the development

process, based on frequent stakeholder testing and discussions. The application is then tested in the real use environment and by actual users, during the user study phase. The final phase includes an analysis of the results and artifacts and publication of findings to guide future work. Following a design-based, user-centered, and ethnographic approach reduces the barrier toward technology acceptance in an otherwise sometimes technophobic environment.

When conducting user studies, there can be cultural barriers to communication. This is especially visible when working with schoolchildren, as rigid social norms arise from a complex hierarchical social structure. For instance, teachers usually initiate and guide learning experiences and conversations, and researchers are considered as teachers. However, equal participation toward collaborative problem-solving is desired. The Bollywood method enables users to communicate freely, from expressing issues in using a specific product or website (Chavan 2005). The Bollywood method was adapted to online collaborative problem-solving. It reduced the challenges arising from computer and gaming inexperience and known cultural barriers to communication, which in turn facilitated meaningful learning experiences that easily extends to other learning goals, domains and environments, and cultures and regions in overcoming cultural barriers to communication.

The Bollywood Method: While conducting usability studies with Asian participants, Chavan (2005) found that users would not share negative feedback out of politeness and were also hesitant in admitting the problems they faced. To overcome these barriers to social communication, she devised the Bollywood method. In the Bollywood Method users are presented with a dramatized scenario, akin to Bollywood *masala* movies, that requires them to take on the role of a larger-than-life character with a specific goal. For example, for testing an airline ticket booking application, users were asked to imagine that their niece is unknowingly getting married to an underground hit man, who is actually already married. The users have to book tickets to

Bangalore with the incriminating evidence in their sole possession to stop the wedding!

Information Access in Education

In education, the focus was on two groups of children: children with developmental disabilities and children from underprivileged regions. For children with developmental disabilities, multiple gesture-based applications were designed, developed, and evaluated. These applications employ the Microsoft Kinect sensor for motion tracking. This work was a collaboration with IBM Research Labs and the Tamana nongovernmental organization that caters to children with special needs in New Delhi (Sharma et al. 2016a, b). The term developmental disabilities is used to refer to a wide range of neurodevelopmental and/or physical disabilities including (but not limited to) autism spectrum disorders, Down syndrome, and other learning disabilities comorbid with ADHD, cerebral palsy, and other motor impairments (DSM-5[®], 2013). Autism is a neurodevelopmental disorder characterized by a lack of motivation for social interactions and difficulty in learning. Interactive technology offers several advantages for children with autism, including controllable input stimulus, multisensory learning environments, and opportunities to customize for individualized learning goals, structured, predictable, safe, and consistent learning environments (Bartoli et al. 2014; Mora-Guiard et al. 2016). Applications can also simulate real-world scenarios in a safe and controlled environment, and the learning is potentially translatable from the virtual to real world, facilitating self-efficacy. Therefore, it is no surprise that various institutions around the world have incorporated technological interventions for children with autism (Bartoli et al. 2014; Parés et al. 2004).

Employing gesture interaction for children with autism has gained favor in recent years with many researchers working toward developing innovative applications to motivate and encourage children to learn and interact socially (Mora-Guiard et al. 2016). However, much of

this research is focused on children from developed countries and is highly individual, as most of the applications are not collaborative in nature. In developing regions such as India, children with autism are still largely underserved. Moreover, there are several challenges toward adoption of novel technologies – from being expensive and catering to a limited group of people to being difficult to maintain and integrate into existing systems. Furthermore, individuals with developmental disabilities have limited access to these technologies, and therefore the digital divide – technical and economic barriers toward technology access – is more pronounced. In order to overcome these challenges, it is important to substantiate the potential of such technologies and build a stronger case for their adoption. This work is the first of its kind by employing gesture interaction for collaboration for children with autism in India. The applications include:

Kirana: The Kirana application was designed to teach the life skill of buying items from a local Indian grocery store by going through the subtasks of decision-making (deciding what to buy), arithmetic (calculating if they have enough money to buy), and social interaction. It was evaluated with children who were previously unable to shop by themselves. An educator provides the task – a list of items to purchase. The children are expected to purchase the items by pointing at the virtual items, pay for them by pointing at the virtual money, and check the itemized bill on the left side of the application screen to make sure the bill can be paid.

Balloons: Balloons promotes social interaction via joint attention, or the shared experiences over a common object, which is a crucial step toward social inclusion for individuals with autism. Joint attention has been linked to language acquisition and social interaction in the later stages of the neurological development of a child. The process of joint attention can be achieved in several ways, “including sharing attention (e.g., through the use of alternating eye gaze), following the attention of another (e.g., following eye gaze or a point), and directing the attention of another” (Dawson et al.

Building Rural Renaissance and Suburban Development with Interactive Technology Solutions in India, Fig. 1 Kirana store application (top left), Balloons

application (top right), and participants try the applications at the school's Diwali Mela (bottom row)

2004). In balloons, two participants have to select the same balloon together, within a 3-second timer, using verbal and nonverbal cues (Fig. 1).

Our overall experiences with these applications suggest that involving different stakeholders, for instance, parents, therapists, and special educators, in the designing process reduces the barriers toward technology acceptance and adoption. Furthermore, applications that can be customized for different individuals, and also diverse learning goals, cater to a larger user group, making efficient use of resources. By taking into account the cultural implications of the environment, socially acceptable interactions can be designed. The work with Tamana is the first of its kind that employs interactive technology solutions for educational interventions for children with special needs in India. This work won the 2015 NASSCOM Social Impact award for Tamana.org (<http://engochallenge.org/winners-2015-using-digital-tools-to-help-people-with-disabilities>) (Figs. 2 and 3).

For the second group, children from under-privileged urban regions, studies with the CityCompass application to encourage children with computer inexperience to collaborate with a foreign researcher were conducted (Sharma et al. 2018, 2019). CityCompass is a virtual language learning application that uses 360 panoramic views of an actual city for collaborative tasks. It was designed by researchers in TAUCHI and Plural, at the University of Tampere. In the application, participants take on the role of either a tourist or a guide, and together they navigate through a series of panoramas to reach a pre-assigned destination. The educational and language learning potential of CityCompass was established in previous work with students in Europe (Pihkala-Posti et al. 2013, 2014; Kallioniemi et al. 2015a, b).

In India, CityCompass was used with children at Deepalaya, a nongovernmental organization focused on imparting education to marginalized children from slums in Delhi. The Bollywood

Building Rural Renaissance and Suburban Development with Interactive Technology Solutions in India,
Fig. 3 CityCompass tourist version (left) and guide version of the application (right)

method was added to CityCompass, and students were provided a dramatic story: of being lost on a school trip in a foreign city, with a sense of urgency, before interacting with the application. This created engaging and immersive learning experiences and improved cross-cultural communication. The results can be extended to online learning systems aimed at cross-cultural collaborations for language learning to other domains and cultures, allowing children from different cultures and backgrounds to experience the globalized world we live in (Fig. 4).

Information Access in Healthcare

In healthcare, the focus was on providing maternal healthcare information for users with low level of literacy, employing gesture-based input and audio-visual output using a Microsoft Kinect sensor, a laptop, and a TV display, eliminating the need to read or write text, as described next in the GILL project (Sharma et al. 2014). India has an acute shortage of trained physicians, and a lack of culturally sensitive health information, social inhibitions, prohibitive gender-based roles, poor

Building Rural Renaissance and Suburban Development with Interactive Technology Solutions in India,
Fig. 4 Deepalaya Learning Center Sanjay Colony (left) and a Deepalaya student using the application (right)

infrastructure, and an overall low health consciousness, especially within rural populations, are all deterrents for opting for professional healthcare. Providing health information initiates open dialogs among community members that lead to better health practices and helps overcome the prevailing social taboos associated with various health conditions. In collaboration with the Indian Institute of Technology – Guwahati, Assam, and IBM Research Labs Delhi – an interactive gesture-based health information system for rural Assamese women was designed, developed, and evaluated.

The application aimed at overcoming participants' inexperience with technology and functional illiteracy, by incorporating gesture-based interaction, which did not require users to read or write. Functional illiteracy means that even with some form of formal education being unable to say read a label on a medicine bottle to understand dosage. This can be a consequence of being unable to read or write (low literacy levels) or being unable to read the specific language on the bottle (high literacy but in a local language). Two gesture-based solutions were implemented in the application: *touching* or using the body-centric gestures to give input to the system, for example, touching one's head to input say a headache and *pointing*, where users pointed at a menu item on the screen. After investigating these interaction techniques, a clear preference for gesture-based

interaction employing local body-centric gestures was observed in the healthcare domain. Using the outcomes of Gill, interactive health information systems have been successfully piloted in clinics across Assam, and IIT-Guwahati won the Gandhian Young Technological Innovation Award for its work, Chetna+ project (Sorathia 2016) (Fig. 5).

Information Access in Agriculture

In agriculture, the prime focus was on the rural Indian farmers in the state of Karnataka. Working with local partners, a speech-based mobile application that provided relevant information was developed (Ruohonen et al. 2012, 2013a, b, c). Employing voice overcomes communication and interaction barriers due to functional illiteracy. Rural India relies heavily on spoken conversations as a primary mean of communication, because of literacy barriers. IBM Research Labs in India built the Spoken Web technology (comparable to World Wide Web) to provide users with voice sites (similar use as websites) that could overcome the literacy barriers to technology access (Kumar et al. 2010). Content on the voice sites could be recorded using a low-end mobile phone and in the local dialect, in order to provide information to rural populations (Kallioniemi et al. 2012; Srivastava et al. 2012). This provided

Building Rural Renaissance and Suburban Development with Interactive Technology Solutions in India, Fig. 5 The experimental setup at IIT-G (top left),

observation room (top right), interviewing participants post usage (bottom left), and a user interacting with the application (bottom right)

to be an effective way to overcome the current digital divide, especially regarding information access, and inspired several other projects.

The aim of this research was to develop viable mobile and multimodal services and business models for rural India to help the underprivileged – starting with agriculture. The application, *Krishi Jnana Vani* (Agricultural Knowledge Voice), provided agricultural information right from “seed to spoon” to local farmers to achieve sustainable agricultural practices. The information was in local Kannada language, which is spoken by 45 million people in Karnataka, and therefore the local farmers could interact in their own language. The voice site had information collected from already installed information kiosks at the University of Agricultural Sciences of Dharwad. These kiosks offered farmers agricultural information in textual format, so that content was recorded into audio format at *Krishi Community* local radio station in Dharwad. *Krishi Jnana Vani* offered information

first about three different crops, sorghum, wheat, and maize, and information about agri-processes such as crop improvement, production, post-harvesting, and pesticides. It was later developed to include information about 40 crops. In addition to technological solutions, successful service deployment requires contextual understanding about the users’ and their needs, the environment, and the local stakeholders. This understanding must be gained without overestimating or romanticizing the capabilities of the people. The major challenge for the bottom-of-the-pyramid people in rural India is access to services and relevant and reliable information. This means that a significant palette of localized voice-based services can be created to improve the situation, even when considering the natural limitations that these services have compared to human-operated services. For example, in agriculture the services can in the simplest form include dynamic information services considering production, processing, and marketing of the farm products and cash crops.

Building Rural Renaissance and Suburban Development with Interactive Technology Solutions in India, Fig. 6 Karnataka villagers interacting with services developed for RuralVoice

Our findings substantiate the potential of utilizing voice-based services and innovative business models for users in developing areas, such as in Asia, Africa, and Latin America (Fig. 6).

Conclusions

As technology become more affordable and pervasive in classrooms, community centers, and through mobile phones, interactive services provide a possibility to improve information accessibility in various areas and to overcome the functional illiteracy barriers associated with the low literate rural men and women. Further, these technologies can provide more innovative and more effective learning environments for children. From embodied interactive application for children with special needs, to language learning through cross-cultural collaboration, to interactive health information systems, and to mobile applications promoting sustainable agricultural practices, this research is actively involved in designing interactive technology and services that overcome literacy and accessibility barriers.

Future work in India focuses in the first phase (2018–2019) on education and healthcare in the context of building rural renaissance and

suburban development. Work in education consists of developing an immersive virtual reality CityCompass application that supports 360° video panoramas on an affordable smartphone placed inside virtual reality glasses, like the Samsung gear. For children with autism, the potential of wearable emerging technologies, such as the Fitbit activity trackers to encourage physical exercise, is being investigated. An internal consortium focused toward improving technology interventions and learning experiences for children with special needs is also being formed. In healthcare, information and learning access is being expanded to healthcare workers and their trainers. Collaboration with Global Health and Development group at UTA is underway with a focus on fostering mHealth applications for mother and infant well-being. The initiatives in India pave the way for designing applications for currently underserved Indian women and children, across schools and health centers in different villages and cities for reducing the digital divide.

Bunyip, The Australian Educational Computer that Was Never Built

Arthur Tatnall

Victoria University, Melbourne, VIC, Australia

Synonyms

Computer systems; Culture; Educational computing

Introduction

Software from organizations like the Minnesota Educational Computing Consortium was utilized in the late 1970s and 1980s in Australian schools, but, good though it was, it created a cultural issue as this software typically had an American outlook. Another example was the Apple][simulation game “Lemonade.” The game was based on making and selling lemonade from a street stall, but the problem was that lemonade stands are almost unknown in Australia. Of course the program had some merit in terms of teaching

students about mathematics and one aspect of doing business, but perhaps there was a better way of doing this. Many Australian schools used the Acorn BBC computer, but it had similar cultural problems, an example being “Suburban Fox.” This was a good game that involved students in acting as a fox to find food and avoid getting killed by a car or in a fox hunt. The fox had to watch out for bright lights when crossing a road at night and be wary of the sound of hounds baying. Again the problem is that this was quite foreign to Australian students.

In 1983 the Commonwealth Schools Commission set up the *National Advisory Committee for Computers in Schools* (NACCS) to provide advice on the implementation of its \$18 million National Computers in Schools Program that was aiming to offer a broad approach computer education in Australian schools (Commonwealth Schools Commission 1983). An immediate problem faced by NACCS was the widespread availability of a large variety of low-cost microcomputers for schools and the problems that this diversity of incompatible hardware and software in schools would present. The short-term proposal was that Commonwealth funds be provided for only a small number of computer systems: those on the “recommended list” drawn up by each state (Tatnall and Jenner 1986). Only these would then be supported by the program. Its longer-term proposal was for a development project to design and build an “Australian Educational Computer.” Apart from reinforcing Australian culture, this project would have had the added advantage of the new computer being built in Australia by an Australian company.

Specifically Designed Computers for School Use in Other Countries

Several other countries had already decided to design and build their own school computers. These included the United Kingdom, New Zealand, Sweden, and Canada. The UK and New Zealand developments were essentially by private industry and produced the Acorn BBC microcomputer and the Poly, respectively.

In Sweden it was driven by the government and the major goal was to assist local industry. The process in Canada was rather like that proposed for Australia and resulted in the development and production of the ICON computer (Tatnall and Leonard 2010).

The United Kingdom: Acorn BBC Computer

In the early 1980s, the British Broadcasting Corporation (BBC) started to work on the *BBC Computer Literacy Project* (Schmidt 2010) with its TV series: *The Computer Programme*. The BBC wanted to base this project around a microcomputer that was capable of doing things such as programming, graphics, sound and music, teletext, communications, controlling external hardware, and artificial intelligence (Schmidt 2010). After discussions with several British computer companies, Acorn Computers won the contract to provide this computer (Tatnall and Leonard 2010) which became the Acorn BBC Model A, (Based on a 6502 processor with 16 k bytes of RAM.) and this was shortly followed by the Acorn BBC Model B (This was also based on the 6502 but with 32 k bytes of RAM and extra connectivity.) (Old-Computers.Com 2009). The BBC Model B quickly became very popular in the United Kingdom and was widely used in its schools. It also became quite popular in several Australian states.

The Compis (Sweden)

In 1981 the Swedish government began a program for a school computer (Kaiserfeld 1996) with two goals: to give industry in Sweden an opportunity in the development of new technology and to provide Swedish schools with modern, inexpensive computers. A Swedish computer company was appointed for its manufacture, and although over 25,000 Compis computers were put into schools, it was never a market success, and production ceased in 1988 (Kaiserfeld 1996).

The ICON (Canada)

In 1981 the Canadian Minister of Education remarked that: “The Educational and training systems and the industrial sector must not see themselves as separate entities, but as partners in

Ontario's future ...” (Stephenson 1981). She announced the need for computer literacy of all students and set up an Advisory Committee on Computers in Education (Goodson and Mangan 1992) that would, among other things, draw up plans for an educational computer to become the standard in schools (Goodson and Mangan 1992). This initiative had a dual purpose: to create a microcomputer explicitly designed for the Canadian educational environment and also to stimulate growth in the Ontario and Canadian electronics industries (Verburg et al. 1987). A Canadian company was contracted to build this machine (although later this was later to join with Burroughs).

The computer's functional requirements included high-resolution color graphics and sound synthesis capabilities, 64 k of RAM, and a local area network form of architecture (Goodson and Mangan 1992). The specifications also required it to support Canada's bilingual (English and French speaking) population. The new computer was to be a combined unit with the screen, processor, and keyboard all in a single case. It was also to include a trackball. The ICON system was designed around the 80186 microprocessor and based on a workstation/file server architecture with no local storage on the workstations. The operating system, QNX, was Unix-like. One significant problem with the ICON, however, was that while there was a large amount of available software for the Apple II and the Commodore PET, the ICON was compatible and so needed its own custom-written software.

The Poly (New Zealand)

The Poly was designed in 1980 at Wellington Polytechnic as a teaching machine intended for use in computer-assisted learning (Bits & Bytes Editorial 1982; Smythe 2007) and to fill a niche market in education. Poly-1 was a networkable machine based on the Motorola 6809 processor and came with 64 k bytes of RAM and a video card to display graphics on a color TV monitor (Bits & Bytes Editorial 1982). Course materials were produced and refined by a team of New Zealand teachers for a variety of applications. Poly was presented as “a reliable, robust,

networked, teacher and student-friendly closed system specifically designed to deliver computer assisted learning across curricula as well as computer awareness, computer studies and support for school administration” (Smythe 2007).

Designing the Australian Educational Computer

This then was the background for NACCS' proposal to designing and building an Australian Educational Computer. There were several reasons for developing this computer (Tatnall 2013):

- So that Australian school children would have access to well-designed computer equipment.
- To reduce the problem that US-designed computers such as the Apple II and Commodore 64 came with the burden of imposing aspects of American culture.
- To provide a development and manufacturing opportunity for Australian industry. It was generally supposed that an Australian company such as MicroBee, which produced a CP/M computer used in many Australian schools, would be a likely manufacturer.

The idea was that the Commonwealth Schools Commission be responsible for the production of an **educational user requirement** and an **educational technical requirement**, while the Department of Science and Technology takes charge of the **system concept study**. If no existing computers were to satisfy the educational technical requirements, then the Department of Science and Technology would draw up an **Australian design specifications** and arrange for the manufacture of pilot and prototype systems (Commonwealth Schools Commission 1983).

Determining the Educational User Requirements

An **Educational User Requirement Working Party** was appointed early in 1985, consisting of educators at all levels from around Australia. It soon produced a report (Commonwealth

Schools Commission 1986a) outlining the many and varied potential educational needs of computer users in schools and the need for integration of information technology concepts into the curriculum. Its report highlighted several critical user requirement issues to be taken into consideration by the Educational Technical Requirement Working Party:

- The needs of various different types of users at both primary and secondary schools
- The nature of the physical, school, and classroom environment
- The variety of applications
- A consideration of modularity, expandability, entry cost, user interface, robustness, reliability, portability, compatibility, and adoption of current recognized standards

Determining the Educational Technical Requirements

The **Technical Requirements Working Party** was set up in 1985 as an “expert” committee with membership reflecting the range of relevant groups and interests from each Australian educational sector, state, and territory. The committee’s report to NACCS was published in March 1986 and contained two main sections (Commonwealth Schools Commission 1986b):

- A technical requirement, which gave detailed coverage to user interface, input devices, output devices, processing resources, networks, telecommunications, and system requirements
- A section dealing with possible implementations of these requirements to satisfy at least three envisaged types of use: personal systems, classroom systems, and school network systems

The idea was that these could be catered for by a family of compatible systems having a common user interface and that at some stage in the future, the way should be left open to connect these systems to computing facilities at the district, regional, state, or national levels (Tatnall 2013) (Fig. 1).

The System Concept Study and the End of the Project

The next steps in the process should have been setting up a system concept study to be followed by a development proposal, but at this stage, the project stopped (Tatnall 2013, 2014). The 3-year government initiative for the National Computer Education Project was at an end and so was its funding. Further development funds from the Department of Science and Technology were not made available, and so work on the Australian Educational Computer ceased (Tatnall and Leonard 2010).

The Bunyip: A Failed Technological Innovation

Innovation can be defined as “the alteration of what is established; something newly introduced” (Oxford 1973), and to be successful, the new technology must be adopted and used. The process of innovation thus involves getting new ideas accepted and new technologies adopted and used (Tatnall 2011), and a new technology will only be adopted if potential users make a decision to do so. With only the two Schools Commission reports to show for the effort expended in designing the Australian Educational Computer, this project could not be considered a success. Actor-network theory (Callon 1986, 1991; Latour 1986, 1991, 1996) could be used to good advantage to explain this failure (Fig. 2).

Like Frankenstein’s monster (Shelley 1818), the Australian Educational Computer was never sufficiently “real” (Latour 1996) to be given a name of its own, but I will call it the Bunyip. (A Bunyip is a creature from Aboriginal mythology that is said to lurk in swamps, billabongs, and rivers.)

The development project for building the “Bunyip” involved the Commonwealth Government, State and Territory Governments, the Commonwealth Schools Commission, the Department of Science and Technology, other State and Commonwealth education authorities, committee members, reports, specifications

Bunyip, The Australian Educational Computer that Was Never Built, Fig. 1 Personal and classroom systems and a possible implementation of a school-wide system (Commonwealth Schools Commission 1986b)

documents, the computer industry, and changes in funding priorities. Various interactions between these actors led to the development of the specifications for this computer, but not to its construction (Tatnall 2013). Getting a technological innovation adopted, or in this case even manufactured, involves convincing people of its value. Convincing other people was almost impossible in this case as, outside the committees and the government, very few people knew about

it. This project really was a team exercise, and no particular individuals stood out or made their presence felt. Perhaps this was a factor in its demise.

Furthermore, at about this time, the microcomputer technology situation changed dramatically with the entry of two new actors into the school market: the IBM PC and Apple Macintosh. When the project was dropped, there was no public outcry – the public did not know about

Bunyip, The Australian Educational Computer that Was Never Built, Fig. 2 Australian stamp showing a bunyip

it. Although we all were disappointed by the decision not to proceed, in light of later developments, we were perhaps relieved not to have created a white elephant like the Canadian Educational Computer – the ICON – which was neither PC nor Macintosh compatible and soon became obsolete. Today the decision Australian schools make in choosing which type of computer to use is between a Windows PC and a Macintosh. Although possibly representing a missed opportunity, the demise of the Bunyip had very little overall impact on computer education in Australia, but it was not entirely a waste of effort as the reports and the specifications documents published by the two working groups are still of value today. Would this project have helped to stimulate the Australian computer industry?

Perhaps if one or more prominent individuals had been prepared to speak out passionately for building the Bunyip, their interestment (Callon 1986) could have assisted it in becoming real, and its future might then have been quite different. This project was about technology, but technology itself had very little effect on its termination.

Conclusion

The dominance, within a few years of the Apple Macintosh and MS-DOS (later Windows) PC, meant that it was probably lucky that the Bunyip project did not proceed and create an expensive white elephant. Perhaps it just comes down to government funding and the establishment of a need for the system. If funding had been available and a successful need established, would Bunyip have been successful? If it had been built, would Bunyip have been able to translate (Callon 1986) to a new form in the face of competition from the PC and Macintosh?

BYOD in the Classroom, Opportunities, Issues, and Policies

Ieda M. Santos
Curriculum and Instruction, Emirates College
for Advanced Education, Abu Dhabi, United
Arab Emirates

Introduction

It is acknowledged that increasingly higher education students are entering the classroom equipped with their personal mobile devices, which they use to connect to the institution network. These students may bring one or more devices, such as mobile phones, smartphones, or tablets, and expect to use these devices for learning purposes. This is a natural process as these devices are part of students' daily lives, and they can easily adapt to their needs and use in the classroom. The widespread ownership of personal mobile technology has given rise to the "bring your own device" or BYOD model where educational institutions encourage students to use their personal devices to support teaching and learning practices both inside and outside the classroom. BYOD, therefore, brings changes to the traditional model where institutions are used to

providing and having more control of technologies students and faculty would use on campuses and classrooms.

BYOD is a significant feature of mobile learning that is stated will go mainstream in education as mobile technology is an integral part of students' lives and essential to their academic success (Brooks and Pomerantz 2017). Another reason for institutions to move towards BYOD is the need to adapt to technological advancements and students' lifestyles, to remain relevant and attract potential students to their programs. Along these lines, due to rapid technological developments, the notion of BYOD will likely expand to encompass wearable devices such as smartwatches and eyewear devices (e.g., glasses) for academic purposes. For example, in comparison with the 2015 survey data, the 2016 EDUCAUSE Center for Analysis and Research (ECAR) survey (Brooks 2016) reported that student ownership of wearable technologies (e.g., smartwatches), and the use of these devices for coursework had increased 150% and 100%, respectively. A further reason for institutions adopting BYOD may be related to their inability to justify costs involved in supplying technology to students, such as computer laboratories and software, when students have their own powerful mobile devices (Sharples 2013). It is also likely that students will prefer to use their devices that are probably newer, better, and more updated than the technologies available at their educational institutions.

The BYOD model is often discussed as providing both opportunities and challenges to higher education institutions. If institutions decide to embrace a BYOD model, then the challenges that can hinder its successful implementation and potential learning benefits must be addressed. The challenges must also be explored with leaders and other parties (Traxler 2016) to develop or update acceptable and supporting policies. The following sections provide a background on opportunities afforded by personal mobile technology followed by a discussion of key challenges related to BYOD, while addressing implications for policies.

Opportunities

A BYOD model can be an attractive option to higher education institutions due to perceived reduced costs, since students use the available technology they own to support academic practices. This might be relevant at times of budget cuts affecting many institutions, which will also impact the provision of resources. It is important to note that while institutions may reduce costs related to less maintenance, and supplying hardware and software to the students, they need to consider financial costs related to improving their network infrastructure capacity to accommodate not only students' mobile devices but also those owned by instructors and staff. Institutions also need to consider costs related to enhancing their network security, by purchasing and upgrading software. Nevertheless, BYOD provides increased opportunities to make more technology available in the classroom, which students can potentially benefit from and develop needed skills for the twenty-first century workforce such as digital literacy skills. In addition, as the devices are available in the classroom, which allow access to online information, sources, and built-in tools and applications, it enables instructors to use those devices in lectures in a variety of ways to enhance the learning experiences.

Furthermore, BYOD offers students more ownership over their learning as they can choose when and where learning will happen, select and customize the tools needed to complete activities, access internet resources and information, and interact with others. Within the classroom, student devices can potentially provide endless learning opportunities ranging from informal to formal usage of the devices. Students, for instance, with an internet-enabled mobile device in the classroom, can search for supplementary sources to enhance understanding of the content being taught, can access videos or take pictures of course materials, complete quizzes, or reach out to experts in the field. Further examples include opportunities for collaboration and participation in instructor-organized activities. An instructor, as exemplified by Song and Kong (2017, p. 42), can

“enact mobile and seamless learning using a project-based learning approach more effectively for the whole course on the learning management system . . . and using different apps such as Google Drive and QR [Quick Response] codes as tools for varied teaching and learning purposes.”

Key Issues and Policies

Despite the opportunities and potential educational benefits, as with any new technology in education, a BYOD model brings its own challenges that can compromise its effective implementation in higher education. The following sections discuss some of the key challenges often mentioned by educators, researchers, and practitioners. While addressing the challenges, the sections also discuss implications for policies.

Inappropriate Use

A widespread concern among instructors relates to disruptions and distractions caused by personal mobile technology. It is common knowledge that during lectures, students use their devices for both academic and nonacademic purposes. While students can be using their devices to take notes or access extra resources related to content, at any time, they may also access social media or other applications to engage in nonclass activities, which may disrupt the class, participation, and student learning. Engagement in nonclass activities such as texting and browsing the internet may lead to instructor reluctance to adopt BYOD, or the implementation of strict policies that ban or limit the devices in class. These types of policies are counterproductive, given the learning opportunities and experiences provided by a BYOD model. Since students will not give up their personal devices, a more positive approach involves developing or adapting existing policies that help decrease the disruptions in the classroom. Considering that students and instructors may have different viewpoints in relation to the value and use of mobile devices in the classroom, more effective policies are those developed in consultation with students, instructors, and other stakeholders on

the appropriate BYOD usage and practices in the classroom, which will meet the needs and expectations of the involved parties.

A policy is needed that encourages regular and updated workshops, seminars or professional development to promote awareness, technical skills, experimentation with pedagogical innovations, and good practices of teaching and learning with technology, as well as exploring examples of BYOD activities, tools, and applications for academic purposes. The planning of these activities should be informed by research outcomes in the field, practical experiences, and understanding of students' practices with their mobile devices both inside and outside the classroom.

Institutional support is crucial to help instructors to address the challenges of today's digital classroom and integrate meaningfully the devices students carry with them into their teaching, adopting innovative pedagogical practices based on learning theories and student-centered approaches that promote engagement with content and activities. Research has shown that when instructors create a classroom environment that encourages active participation, it helps reduce the possibility that students will be causing disruptions with their devices (Berry and Westfall 2015). Similarly, Brooks and Pomerantz (2017) exemplified that students who used their smartphones purposefully to complete in-class activities, which also involved instructor-led activities, were less likely to use their devices to engage in nonclass activities. Moreover, instructors' engagement in professional development and experimentation with mobile technologies can help change their attitudes towards disruptions (Dyson et al. 2013).

Digital Inequalities

Despite widespread mobile technology ownership, it is not universal. For example, in comparison to developed nations, the Pew Research Center (Poushter 2016) reported that emerging economies lag behind smartphone ownership; however, according to the survey results, in a number of emerging and developing countries, more individuals are connected to the internet,

and smartphone ownership is climbing at an extraordinary rate. On the other hand, in some of these countries, there may be issues related to cost of internet access to maintain connectivity, and low bandwidth, which can restrict the use of online sources, downloading files, or other activities.

Therefore, a BYOD model can give rise to issues of digital inequality, preventing some students from participating in mobile-based educational opportunities. It can potentially exclude students, for instance, who either do not have access to the latest technology, applications and internet connection, or do not have access at all to a device to be able to participate in the learning activities. In addition to digital access, students can also be disadvantaged if they do not possess the knowledge and skills to effectively use the devices as learning tools.

There is certainly a need for a policy that will address equity issues unique to BYOD. In the same vein, Traxler (2016) reminds us that any policy must recognize that mobile technology is unlike other technologies in terms of equity that requires access to hardware, tools, applications, and ongoing internet connectivity. Policy needs to address the variety of mobile devices students bring to the classroom, with different operating systems (e.g., Android, iPhone), some more advanced than others, which have implications for participation in activities. Instructors, for instance, may not be able to use an application (app) that does not run across the different operating systems. Therefore, they must develop awareness through workshops or training of academic applications that will work across different mobile platforms or consider alternatives such as browser-based activities or cloud computing if all students have internet connectivity on their devices. Activities may include web-based response systems where multiple devices can be used to answer quiz questions, or access Google apps such as Google documents, and storage of data using any device and from any location.

As hardware and software keep developing and improving, the challenges related to instructors not being able to organize activities due to

different mobile operating systems should soon be resolved with device-agnostic applications. Therefore, despite the diverse BYOD environment, the software can be homogeneous, meaning that students owning iPhones or Androids, can run the same application or activity on both devices (Norris and Soloway 2015), avoiding disadvantaging any student inside or outside the classroom. The idea of device-agnostic facilities reinforces the need for a policy that considers frequent delivery of workshops to allow instructors to keep up with technological developments and new opportunities. Independently of technological advancements, prior to planning activities supported by BYOD, it is critical that instructors conduct a needs assessment to learn about student devices and relevant technical limitations to promote equity in the classroom, and beyond. This is paramount as, for instance, learning activities may be organized in the classroom but will extend to other contexts, later returning to continue in the classroom. In this case, instructors need to make sure all students will have access to a functional and internet-enabled mobile device.

Information Technology Issues

Effective BYOD implementation will certainly require robust network infrastructure to support teaching and learning practices, which has financial implications for institutions. Institutions will need to adapt their existing policies to accommodate the BYOD model that relies on multiple connections and 24/7 connectivity to meet student and instructor expectations and needs. Song and Kong (2017, p. 43), for instance, reported that “due to unstable internet connection and the slow data transmitting speed, they [instructors] felt disappointed, even annoyed when using BYOD in their pedagogical practice. This slowed down the lesson progress and discouraged them from using BYOD in class.” Thus, lack of reliable and stable internet connectivity does not only lead to frustrations but also prevents students from participating in learning opportunities. It is important to note that a policy addressing network infrastructure needs to be sufficiently wide, yet detailed, to allow emerging technologies such as

wearable devices and the “Internet of Things” that connect any device to the internet.

Furthermore, multiple devices are available in the classroom and, as mentioned previously in this entry, with different operating systems and applications, which may complicate the provision of technical support. Information technology (IT) personnel, used to managing and supporting controlled technologies provided by their institutions, may face challenges to support a potential unlimited number of technologies and models owned by the students (Traxler 2016), which they may not be familiar with. On the other hand, students are familiar and comfortable with using their everyday mobile devices and would know how to work with their devices and fix technical problems. Students, as emphasized by Brooks and Pomerantz (2017), may figure out solutions for the technical problems on their own, or search for online resources such as YouTube videos that teach them how to solve problems related to their devices, or use their friends or network who can help them fix the problems.

The issue of whether institutions will provide technical support or not for student personal mobile devices is debatable, ranging from some educators arguing that support should be provided to transferring the responsibility to the students for repairing and maintaining their devices (Santos 2015). There may also be financial implications related to technical support as institutions may need to hire more IT personnel since the workload may increase. Therefore, institutions will need to define a clear policy that states what kind of IT support is available to the students.

A further challenge widely discussed is that the BYOD model can bring about a series of security concerns. It is likely that traditional measures and procedures previously adopted by institutions to secure access to their services and information will need to be revised to minimize risks. Security risks may range from the devices bringing malware and viruses to the institution network, which can freeze the system, and lead to theft of institutional data, to loss of unprotected mobile devices containing institutional

information (Santos 2015). Strong policies will be needed to secure the institutional network, systems, stored private and sensitive information in addition to implementing on-going measures to enhance security systems. Security measures employed by institutions are currently varied, ranging from registering personal mobile devices, which enables tracking the activities performed by these devices, implementing a dedicated virtual network to BYOD separated from the institution network that store private data and applications, to enforcing strong authentication mechanisms such as student and instructor passwords.

To be more effective and comprehensive, policies related to security should be developed through different departments including those for IT and Human Resources to ensure alignment and coverage across departments. In addition, students should be involved in the development of security policies to promote more commitment on complying with the policies. Policy should additionally address frequent training for students and instructors to help them understand the institutional policies, develop awareness of security threats, and learn strategies to decrease potential risks. For example, training sessions could cover why software should be installed and updated on devices and the importance of setting up passwords.

Conclusions

A BYOD model can potentially bring benefits to higher education institutions ranging from reduced costs to learning and teaching opportunities both inside and outside the classroom. There are key challenges attached to this model that can hinder its successful implementation, including inappropriate use of personal mobile technology in the classroom, digital inequalities, and information technology issues. These issues must be addressed to support effective BYOD implementation, which aim to enhance teaching and learning practices. To address these issues, institutions will need to either update their existing policies or

develop supporting policies that are unique to BYOD, or consider a combination of both approaches.

While the issues discussed in this chapter are not unique to one country in particular, policies need to be developed taking into account the culture, context, the institution itself, departments, and, necessarily, course level needs. Effective policies should be developed in collaboration with key stakeholders from the institution, including administrators, students, instructors, and information technology personnel to address the issues discussed in this chapter and beyond. Beyond this, technology keeps developing at a rapid pace and will certainly bring other challenges and concerns. Therefore, policies must be flexible to accommodate the rapid technological advancements that will expand the notion of BYOD and will impact, among other things, usage, attitudes, behaviors, and the need for innovative teaching and learning practices. Finally, BYOD policies need to be informed by research findings in the field, by practice and experiences, as well as needs assessment conducted with students and instructors.

Definition

Mobile devices today include a camera that offers the functions of both still photos and video recording. These functions were once seen as expensive and difficult to involve in learning. Now, learners have access to take photos, video recordings, and edit and publish all within one device. When camera technology is used in the classroom, it can promote valuable learning outcomes and higher-order thinking and develop traditional

and new literacy skills (Henderson et al. 2010; Schuck and Kearney 2006).

Mobile devices and laptops have become popular tools to harness technology in education. Digital technology has the potential to create an environment that is student centered as it allows access to learning through a variety of modes and resources. The inbuilt function of a camera offers educators to drive opportunities that support students to demonstrate learning, self-reflect, and provide feedback. Pedagogy practices will affect the integration of digital technology.

Introduction

Creative and effective integration of technology needs to be married with new pedagogical practices. The power of technology is driven by a teacher's pedagogical practices. For example, technology will support and aid in the implementation of a constructivist paradigm (Prensky 2008). The teacher's role is not to feed knowledge but demonstrate how to develop and find new knowledge. Teachers should see their facilitating role as a supportive, intellectual role. They can be there to support digital literacy skills and ensure the function of technology is applied appropriately. They are the experts in supporting literacy skills and integrating technology and tools correctly (Shaikh and Khoja 2012).

If teaching pedagogy does not change, technology will not be used effectively. Traditional teaching methods of teacher-centered and controlled lessons do not appear to create innovative, lifelong learners. Delivering information within a teacher-centered environment is not effective when it is mediated through technology (Shaikh and Khoja 2012). The teacher's role is a facilitator because when teachers are still relying on lecture style teaching, technology hinders the learning environment for students (Prensky 2008).

Constructivism emphasizes that learning is student-driven. Learning is active through knowledge construction, conversation, articulation, communication, collaboration, and reflection (Shaikh and Khoja 2012). Prior knowledge is

used to help discover new concepts rather than students being told what to learn. Students become engaged in their learning, and the teacher plays a vital role to shape these learning conditions (Collis and Moonen 2006).

When integrating the technology, teachers should not primarily focus on the integration of apps. "There's an App for that" is a saying that implies education can be driven through a digital platform. The focus of finding apps to reinforce and drive learning moves away from the teacher's role and makes the assumption that apps can replace the teacher and skills that are essential for today's learning environment. The emphasis moves away from student-driven work created by technology that may not marry with open-ended tasks to create stimulating research.

Learning Environments

In today's learning environment, it is imperative to provide multiple opportunities for students to engage in their learning and promote learner ownership and voice in the learning process (Oliver and Herrington 2001). The camera within mobile devices provides these opportunities. The integration of mobile technology does not need to focus simply on external apps, websites, and software. Teachers need to recognize the potential of the inbuilt functions found in digital devices that can help support constructivist paradigm.

Students and teachers collaborate to create personalized learning environments that generate creative, meaningful learning. Student's roles in the classroom need to be active roles, one which is supported by collaboration, conversation, dialogue, and sharing of knowledge to open up new and exciting ideas (McLoughlin and Lee 2010). Teachers provide opportunities for the learners to find relevant information, to work in groups and share ideas, and to validate knowledge.

Technology provides opportunities for learning and investigating that will give learners the knowledge and building blocks to become successful, lifelong learners. Digital technology allows students to find this information and

explore multiple resources. It allows learning through multimodal learning, using a range of resources to research and problem solve. It gives students opportunities to collaborate inside and outside the classroom. Teachers need to reconsider their pedagogy to ensure students are active participants and co-producers of their learning. Technology provides access to information. Being passive consumers of prepackaged facts will not support the wider potential of lifelong learning (McLoughlin and Lee 2010).

Communication facilitates students' ideas, information, and emotion. Still and video-based photography can provide multiple opportunities for student engagement. This technology can be used as an analyzing and observation tool to enhance learner performance. Using digital video as a tool can support reflection of student learning (Henderson et al. 2010; Schuck and Kearney 2006).

Valuable learning outcomes have been related to the use of video productions. Higher-order thinking skills have been present in the use of videos. High-order thinking skills include problem-solving, reasoning, planning, analyzing, creating, and questioning skills. Through using these productions, learners become aware of the process of learning and have the potential to reflect on their learning. They develop the necessary skills to identify how they learn and why they are learning (Henderson et al. 2010).

Applications

In the past, issues such access to digital cameras, access to photos and storing of photos and post-production editing, and creation hindered the integration of still and digital photography (Henderson et al. 2010). These issues no longer exist due to the inbuilt camera and abilities of current digital devices.

While the following sections specifically focus on the iPad Air, other digital devices offer similar properties. The iPad Air embeds a 5-megapixel iSight camera, offering HDR photos and videos. Functions within the camera setting are simple

and easy to use, and users have access to multitude of functions that are easy to navigate and use. The design of the camera allows for a simple, quick transition between still photography and videoing. Users push one button to capture a photograph or commence video recording. Autofocus assures the user and takes away any manual complications of photography. At the push of a button, information has been captured. Users can navigate the screen with the simple large design buttons.

Photographs and videos are automatically stored within the iPad and offer quick access. Editing tools such as rotation, crop, filters, and enhancement of colors and red eye reduction are easily accessible when capturing a photo or video and occur with one tap of a finger. Sharing of photos has become even easier as the functions of the iPad allow multiple options for sharing such as links to open in another app, email, message, social media, copy, print, and photo stream through iCloud.

Still photographs give authentic opportunities for evidence of learning in the classroom. Teachers can use video recording to monitor the development of literacy skills such as reading. Students can video themselves participating in classroom activities and reflect on their participation and learning. These videos can be used as a form of communication, within the classroom and with the wider community such as parents and carers. Students collect and collate evidence of their learning and create digital learning portfolios. Digital portfolios can be created to give students the opportunities to reflect on their learning process. This will give them opportunities to share what they have learnt and how they have learnt it.

The camera function has been a valuable resource to capture student learning. Camera technology has enable students to showcase their work and development of learning within unit topics. The camera has been a valuable resource that has been adapted to meet the needs of all students – from Foundation to grade 6 primary school students. Due to the fact the camera captures the work of the student, it has the potential to complement the work produced, regardless of their age. Digital portfolios have been a key to

capturing ongoing learning within a lesson or series of lessons in primary classrooms from Foundation to grade 6. The following sections related to practice, observations, and research in one primary school.

Within the junior primary levels, the camera is a function that can be used in most lessons. It is a valuable tool to showcase ongoing student learning and achievement. Foundation students were introduced to the camera and have used it as a tool for learning since commencing the school year. Throughout the year it has assisted teachers to monitor student learning and progress without having to rely on written responses from students. By implementing camera technology into these classes, students have been able to articulate their learning and have a record of their learning. Rather than depending on written responses, teachers have captured more learning by allowing students to reflect and articulate their learning through audio responses to questions, evidence of learning through photographs and articulation of their learning through video examples. Such record would otherwise not be available due to the lack of literacy skills of most Foundation students.

To help support the development of the skills associated with using the camera function, teachers in Foundation classes were supported with assistance from the digital technology leader. The institution and leadership is one of the four key components that impact on the integrations of technology. Without the necessary support and understanding of how these components work together, technology has the possible effect of limited integration (Collis and Moonen 2002).

Introduction to the camera and digital learning portfolios commenced through small-group guided reading and writing sessions. The teacher and digital technology leader guided the students to participate in a conversation that discussed the purpose of digital portfolios. Students discussed the features of texts and were guided to generate a title for their digital book. This activity gave ownership to the students and an understanding of how their digital book will be used at school and how it will be different to hard copy books (that it

would contain videos and pictures of their learning). Students generated the title and drew a picture on the front cover. The technical skills of taking a photo and adding it to their book were the initial skills taught to the students.

Team teaching was used to get the Foundation students confident and knowledgeable with using the technology at school. Over three 1 h sessions, two teachers worked with a small group of students to show them the technical logistics of the iPad. These sessions were shorter than expected due to the fact students picked up the skills quicker than expected. The extra support given to the classroom teachers was a critical factor to build student knowledge and confidence to use the device and camera independently.

Within the grade 1 and 2 classes, it is common to have an iPad camera accompanying a mathematics session. A fundamental part of mathematics in the junior grades is to use concrete material to show learning. Students will take a photo of their learning or a video recording explaining the work they have completed using the materials they manipulated. Prior to this, students were unable to keep a record of their work if it was created out of concrete materials. Drawings and hardcopy interpretations were previously the only way to keep copies of work completed when using concrete materials. Although at times, the hand drawn copies were not true reflections of the work they had completed. Since the introduction of cameras, video footage shows the work students have completed with them articulating their learning using correct mathematical language.

Although student reflection is seen as one of the most powerful learning tools for learning outcomes, it is rarely used in classrooms in conjunction with this technology (Henderson et al. 2010). Students can utilize the camera and the technology as tools for self-reflection, but usually requires a suggestion from the teacher.

Over the course of a term, the camera was an integral tool to assist in the creation of daily learning reflections in grade 5 and 6 classes. Photographs showed the development of the learning and building throughout the project and video

recordings were used as reflections and progress of their learning. These reflections were student led with students discussing their learning. In their videos students discussed learning opportunities and “learning hurdles.” They discussed what they had discovered during the session and what problems (hurdles) they had faced. Students self-reflected on the way they could solve these learning hurdles. This reflection ensured they were ready for the next session with solutions to issues and problems, and they knew the direction for their future learning.

The platform used to collect the work and create digital learning journals was Book Creator. The app was chosen due to the simplistic functions and layout used to create books. Students created their own books that related to their learning. The emphasis was on the student actively inputting information which was appropriate to their learning needs. This supports a constructivist paradigm as the app is student centered, allowing learners to make choices throughout the learning process, to reflect on their learning, and to communicate new ideas and knowledge (Oliver and Herrington 2001). Students obtain the relevant information and then build knowledge to solve problems or work through a task. The teacher provides the scaffolds for students to participate in higher-order thinking, problem-solving, and decision-making (Oliver and Herrington 2001).

Summary

These ideas can be used as an example of student learning and engagement through harnessing the use of an inbuilt camera. The capabilities of digital technology go beyond the use of and emphasis of outsourced resources such as websites, apps, and digital programs. When integrating mobile and digital technology, inbuilt functions should not be overlooked. The camera in an iPad offers photography and video recording. This technology can provide multiple opportunities for student engagement and promote higher-order thinking. The uses of this technology can be used as an

example of how to integrate technology into the classroom that promotes high degrees of student initiative.

Computer-based assessment; eExams; Equivalent year level scaling; MAPLE computer algebra system; Measuring impact of innovation; SAMR educational model; TPACK framework for technology in education; Transformation of learning with computers

Educational Expectations

Conventional educational attainment expectations for school students are generally defined by curriculum documents in each jurisdiction. However, new technologies disrupt societies, so it is pertinent to ask how computers have changed educational expectations. Robert Heinlein put this into perspective in a short story (1957). The protagonist is Holly Jones. She is 15 and a spaceship designer: “I’m very bright in mathematics, which is everything in space engineering, so I’ll get my degree pretty fast. Meanwhile we design ships anyhow. I didn’t tell Miss Brentwood this, as tourists think a girl my age can’t possibly be a spaceship designer.” This demonstrates some early aspirations of how education might change in future where lunar habitats become well established.

Outside education, business process reengineering is the practice of re-designing work, particularly when using new technology to reduce costs (Davenport 1993). Davenport commented on the role of computers in changing business practices: “...Information and IT are rarely sufficient to bring about the process change;

most process innovations are enabled by a combination of IT, information and organizational/human resource changes” (p. 95).

When we look at societal use of computers, we see large changes. Banking and travel are usually identified as areas of activity most changed by the application of digital technologies. Internet banking, crypto-currencies, and online commerce have greatly reduced the need to visit a bank branch. Similarly, travelers can book their own flights online, and arrange hotels and tours the same way. Digital technologies are a growing digital component in global trade, with the world’s top six largest companies digitally dependent (Statistica 2018). Four of the top 50 firms by revenue are also digital companies.

Ranking of the companies 1–100	Market value in billion US dollars
Apple	926.9
Amazon.com	777.8
Alphabet (Google holding company)	766.4
Microsoft	750.6
Facebook	541.5
Alibaba (online sales site)	499.4

There is therefore a contrast between expectations of educational change and actual change in the commercial world. The commercial world is the one into which school students will grow. Therefore, educational leaders have an imperative to grapple with this growing schism.

The Challenge

This dichotomy provides a significant challenge for educational theorists and researchers. There have been two noted responses by theorists, the TPACK framework and SAMR model. Koehler and Mishra (2008) introduced TPACK as a way of looking at the key role of technology when teaching online. However, this focused on the method of teaching, not the content. Puentedura (2012) went further and theorized that computers would first substitute for common tools (e.g., keyboard replacing a pen), then augment those tools. Later,

in a transformation phase, the computer would allow for significant task redesign, leading to redefinition of learning to that which was previously inconceivable. This transformative perspective was predicted by Downes et al. (2002, p. 23) and aligns with Fluck's three phase model for ICT policy development (2003, p. 139).

The challenge for researchers arises from the need to measure change. Educational research frequently looks at proposed interventions, generally with the intention of improving learning. Two classical kinds of measures are preferred for this kind of work. The first is null hypothesis statistical testing, with a *t*-test or similar used to confirm a new process makes a difference to learning when compared to previous processes. The significance of such a correlation measure is established by a *p*-value, which demonstrates the unlikely possibility of the result being accidental or by natural variation.

The second class of measures of improved learning includes effect size. Lopez et al. (2015) stress the importance of citing the effect size, because this dimensionless measure is independent of sample size. Effect size can be calculated in several ways: Cohen's *d*, using the pooled standard deviation of the control and experimental groups is most commonly found when conducting *t*-tests; partial eta squared has mostly been reported in studies using ANOVA; adjusted R^2 has been associated with regression analyses; and Hedges's *g*, which applies a correction for small samples (Lopez et al. 2015, p. 108; Tamim et al. 2011). Effect sizes for the use of computers in education have been quite modest with "the average effect size ranging between .20 and .47 standard deviations" (Karasavvidis 1999, p. 2). Effect size calculations are predicated on the test scores being distributed in a near-normal way and on the standard deviations for pre- and posttests being similar.

With transformative applications of computers in the SAMR model, educational researchers have a difficulty in identifying a common scale from which to calculate the effect size of a learning innovation. Following the TPACK framework, if the researcher is using a computer to teach the

same content in a new way, then a standardized and calibrated assessment of educational achievement can be administered to both the control and experimental groups before and after the intervention, with the Solomon four-group design overcoming external validity weaknesses caused by pretest sensitization of subjects. In such research designs, the implicit assumption is the pre- and posttests will accurately measure student educational achievement at a point in time.

For transformative applications of computers, the radically different educational content may be such a departure from the conventional curriculum that students will have no prior knowledge whatsoever. This does raise an ethical question concerning the emotional impact of a pretest assessment in which virtually all students will likely have a negative experience. The research design parameters violate simple humanity, so methods are sought which give the required validity and yet provide a positive emotional experience to the research subjects.

Using Computers in Assessment

There is another aspect of teaching new content which is impossible to deliver without computers: assessment. If computer use is transformative, it will be essential in assessment (Fluck and Hillier 2017). This also makes the pretest/posttest paradigm difficult. If the learned skills can only be realistically demonstrated through student computer use in the posttest, then protocols would dictate the pretest should also depend upon the same mode of assessment. A complication might be the interference effect of the operational skills required to use the software intended for use as part of the educational intervention to be studied. If operating this particular software is in fact an element of the intervention, then its inclusion in the pretest is contraindicated.

The difference in modality of testing became a matter of national concern in Australia in 2018 when standardized testing in schools was conducted both on paper and on screen. Approximately 20% of school students undertook the

testing on screen. Severe doubts were raised about the comparability of the results from the two modes, with the testing agency “acknowledging that year 9 students who sat the writing test online performed better on average than those who completed the traditional pen-and-paper version” (Robinson 2018). The testing agency subsequently released the results using a common mean scale score and reported effect sizes for any differences over time (Australian Curriculum, Assessment and Reporting Authority 2018). This demonstrates national bodies are aware of the modality issues, and map test scores onto a common scale to allow effect sizes to be calculated.

Possible Solutions

Puentedura (2012) has reported transformative “redefinition” uses of computers in school education with an example effect size of 1.563 (Salomon et al. 1989). This is in the context of an average or hinge effect size of 0.4 for educational interventions (Hattie 2009). The Salomon et al. effect size of 1.563 provided the greatest impact in Hattie’s list of meta-studies “Teacher estimates of student achievement.” Salomon et al. used a research design with three randomly selected parallel groups of students. All subjects were pre-tested with a group-administered standard test of reading comprehension (p. 622). Posttesting comprised a metacognitive reconstruction task, another version of the reading comprehension test and a delayed essay writing task. The researchers undertook structured equation modeling and did not actually calculate the effect size. This was drawn as Hedges’ g from the meta-study by Pearson et al. (2005). Puentedura’s reliance on this study and meta-analysis was criticized by Hamilton et al. (2016).

The Salomon et al. study is useful because it points to a multiplicity of achievement tests both at the pretest and posttest stage. The research design explicitly used a different version of the reading comprehension test for the posttest. This technique is sometimes used to avoid memorization – where the student recalls the same item on

the pretest and responds to the posttest informed by that recollection. Test design can be influenced by the choice of item-response theory or Rasch modeling. Item response theory allows test elements to be analyzed for difficulty, which assists when collating scores. Rasch modeling goes further and allows scores to be mapped onto the same invariant scale. We can presume that Salomon et al. mapped the results of the different reading comprehension tests onto a common scale to allow meaningful comparisons. In a similar way, transformative educational computer-based activities may need a different posttest to calculate an effect size.

One possible way forward in transformative or redefinition applications of computers in education is to look at learning achievement in terms of years of schooling. Normally, an effect size of 1.0 corresponds with a change of one standard deviation (Coe 2002, p. 3). Glass et al. (1981, p. 102) have asserted that an effect size of 1.0 corresponds to the normal learning achievement in a year in elementary school. However, Wiliam (2010) found this relationship varies according to the age of the student, becoming smaller for older year groups. Learning progression reduced from one standard deviation per year in Grade 4 and reduced to 0.27 in Grade 8 (p. 116).

There are perhaps two justifiable ways forward. Where the transformation involves learning material relevant to a higher chronological age than that of the student subjects, Wiliam’s progression could be used to measure the impact in terms of years of advanced standing. This faces a minor problem in that Wiliam’s progressions differed slightly for Mathematics and Reading, so the alignment between age and maturation is not precise. The other possible way forward is to map both pre- and posttest results onto a curriculum-age scale. A curriculum-age scale is one where each item of learning is situated in a particular schooling year and is the way most curricula are presented. If the transformative intervention aspires to teach material 3 years in advance of the chronological age of student subjects, then this would be the point on the curriculum-age scale indicated by test scores. Such an approach

allows for the pretest and posttests to be different, since each test points to a different age level on the scale.

Practical Example

The Calculus for Kids project (Chin et al. 2017) epitomized this transformative approach, asking Year 6 (12-year-old) students to learning how to solve real world problems using integral calculus, with MAPLE computer algebra system software as an aide. This skill is not normally taught until Year 12, so the posttest used items from 1st year university examinations of integral calculus (presumed to be Year 13 on the curriculum-age scale). Key to the assessment of learning achievement in this project was student computer use.

As shown previously, the method of calculating effect size varies between studies. Robust research designs rely upon the same pre- and posttest to determine the effect size of an intervention. However, other methods are also used. Tamim et al. (2015) cite a large effect size of 2.066 for a study of tablet use (Huang et al. 2014). Huang et al. (2014) used different pre- and posttests containing 26 and 14 multiple-choice questions, respectively, but validated these through Cronbach's alpha (α , for reliability) and an expert review group for validity. In consideration of these factors, the researchers resolved to aim for a large study and used Cohen's d for reporting the effect size.

Approach

Traditionally, students have been taught how to find the integral of a mathematical function using a series of rules deduced from first principles. This helps students to understand how to integrate a new function in the future. However, as the catalogue of integral functions grows, the use of poorly memorized results using "first principles" can impede practical calculation. Therefore, professional engineers use a variety of specialist software to "crunch the numbers" although they also need to understand the process and its application to obtain sensible and accurate results. One might

argue that reliance on computing equipment in engineering is analogous to the widening use of word processors in newspaper offices in lieu of pens. There is certainly a discussion to be had about the way these technologies redefine the underlying skills or their acquisition.

The main conceptual tools for the study were Rogers' theory of innovation adoption (2003), the nontemplate problem-solving method of Allen (2001), a realistic mathematics education approach (Gravemeijer and Doorman 1999), and a methodology developed for the transformational use of ICT in school education. This methodology combines professional software tools with multimedia instructional materials. The project therefore set out to answer the following research question:

RQ1: What is the effect on learning achievement of transformational computer use in one mathematical education topic for Year 6 students?

Method

Participating schools were recruited from five Australian states, ensuring a wide range of locations and socio-economic backgrounds. Local facilitators were chosen by each participating school and attended a training session at the University of Tasmania. The training course for facilitators inducted them into higher-level mathematical areas, by taking them through the student learning materials consisting of colorful multimedia animations. In each package, teachers were provided materials for 12 1-h modules to be taught over 6 weeks with links to worked examples in Maple worksheets and extension activities for students to autonomously consolidate learning.

The Calculus for Kids learning module was designed for Year 6 students in their regular classes where everyone could use a computer for each lesson. Schools with both 1:1 laptop classes and computer laboratories were included in the study. Our initial preference was for situations where every student used a personal laptop computer. If this was taken home each day, that promised additional time on task. However, this ideal was not

always met, and some classes were able to access the learning module in a school computer laboratory at specific timetabled sessions. Maple was selected as the supportive software because several of the researchers were familiar with it; to ensure students were not disadvantaged in future mathematics learning (it uses conventional notation); and because the study was supported by an industrial partner in the research (Maple 18-2016).

The students in this study were randomly drawn by each participating school. Given that in most cases an existing class was selected, the regular teacher often agreed to be trained as the facilitator in our methods. The classes reasonably represented students across Australia at this level, without bias as to rurality or social advantage (Table 1).

The ICSEA (Index of Community Socio-Educational Advantage) is a scale of socio-educational advantage that is computed for each school (Australian Curriculum, Assessment and Reporting Authority 2015). The ICSEA is constructed so the median score is 1000 with a standard deviation of 100, and incorporates parental occupation/education, remoteness, and indigenous proportion of students. Lower values represent greater educational disadvantage.

The study used published data on numeracy skills at each school (NAPLAN) as a proxy for aptitude on a curriculum-age scale. This took the place of a specific pretest. The posttest positioned students onto the same curriculum-age scale. It

was designed by one of the authors, a nationally awarded teacher of university engineering, and used items from 1st year university engineering calculus examinations.

Results

Between June 2010 and April 2016, 434 students in 23 classes at 19 schools in 5 (of 8) Australian states completed the Calculus for Kids learning module. The module was taught in Tasmania, Queensland, Victoria, South Australia, and New South Wales. The students were selected to be in Year 6, generally the final year of primary school (changes in Queensland meant the Year 7 cohort moved from primary to secondary school during the period of the research). The mean age of students was 11.96 years, with the youngest 9.97 years and the eldest 13.82 years.

Analysis showed there was a small but significant difference in posttest scores for male students ($M = 13.30$, $SD = 0.39$) and female students ($M = 13.38$, $SD = 0.33$; $t(432) = -2.166$, $p = 0.031$, two-tailed). So, the male students appeared to perform less well. However, when the pretest curriculum-age scale levels were subtracted from the posttest curriculum-age scale levels, the gender differential became insignificant: $t(432) = -1.38$, $p = 0.169$). There was also a small and positive correlation between school ICSEA value and student posttest curriculum-age scale level ($r = 0.168$, $n = 434$, $p = 0.000$), with higher levels of social-economic status and geographical advantage value associated with higher levels of student achievement. This corresponds with expected findings; the correlation is small though significant.

Calculating an effect size for transformative interventions such as this presents several methodological difficulties. Traditionally, effect size is calculated as Cohen’s d based upon the difference in achievement obtained from the same or calibrated pre- and posttests. As previously stated in this study, there were strong pedagogical reasons for omitting any pretest, so NAPLAN results were used instead. The following achievement results were obtained from the project (Table 2).

These values give an effect size based on Cohen’s d of 22.19. This is extraordinarily high,

Challenge of Transforming Curricula with Computers, High Impact Interventions and Disruption, Table 1 Demographic data for Calculus for Kids

Variable	Value
Males	235
Females	199
Total students	434
Minimum ICSEA	873
Maximum ICSEA	1197
Mean ICSEA (s.d.)	1042 (82)
Mean age on the day of the posttest (s.d.)	11.96 (0.74)
Minimum age	9.97
Maximum age	13.82

Challenge of Transforming Curricula with Computers, High Impact Interventions and Disruption,
Table 2 Student achievements for Calculus for Kids

	Mean	Standard deviation	N
Year level on curriculum-age scale – pretest	6.55	0.24	434
Year level on curriculum-age scale – posttest	13.34	0.36	434

since an educational intervention is considered significant if it has an effect size greater than 0.25 of a standard deviation using a “rule of thumb” (Tallmadge 1977, p. 34) or 0.4 (Hattie 2009) using Cohen’s *d*.

Discussion

The effect size is very large (>0.8) (Cohen 1988). This finding is important, because much research to date has compared the impact of computer use on learning the same content without computers. When contemplating significant curriculum reform built on an assumption of universal computer access, this very large effect size provides evidence in support of a transformative approach.

The outcome from this project has provided evidence that children as young as 10 years old can use computers to demonstrate higher order thinking when freed from contemporary curriculum and reporting constraints. The power of this evidence is increased by the geographical and social diversity of the participants, providing impetus for radical reform of learning. Policy makers require these practical demonstrations of curriculum transformation with computers to inform the community and make political decisions about the content of schooling palatable and feasible (Kozma 2011, p. 27). This is particularly true in the case of disruptive innovation (Cerna 2013, p. 14).

The researchers have been asked if the Year 6 students really understood integral calculus. The response is students generally passed the university test designed to assess this specific learning achievement. A counter-argument is the students had assistance, in the form of the computer software they used when solving the posttest problems. The Calculus for Kids students needed to know, what mathematical tools to use, when to

use them, and how to use them. This required understanding of the concepts within integral calculus and their application. It is clear there are difficulties when thinking about the impact of computers when transforming curriculum, but there is a clear imperative to do so given their pervasive use in professional and business life. As with any technological innovation, its use replaces old skills with new ones. In Calculus for Kids, the skills to operate the Maple software replaced the mechanical memorization of algebraic formula manipulations. The consequence was that students were able to solve real world problems using integral calculus, which is indicative of higher order thinking.

The study only demonstrated accelerated learning achievement with elementary school students. However, analogous processes could be trialed at other educational levels. For instance, 1st year undergraduates might be able to achieve learning outcomes at the Masters’ or even initial PhD candidate level. Year 10 students may be empowered to demonstrate understanding from 1st year degree courses. This would be a significant outcome for transformative uses of computers in education.

Conclusion

There is no doubt that school education suffers from plurality of control and the inertia evident in any large system. Both educational leaders (Oates 2009) and students (Barrance and Elwood 2018) have expressed concerns that innovations and assessment reforms are proceeding with undue haste. Society needs to contemplate the growing disjunction between the pervasive use of digital technology in professional life and the lack of transformative curriculum changes.

This raises significant difficulties for educational researchers, where the “gold standard” of effect size for evaluating innovation impact needs readjustment. Transformational and redefinition uses of computers make it possible to teach new concepts, not currently in the age-designated curriculum for student subjects. The conventional use of “effect size” comes under increasing strain in

such circumstances. Already there are a variety of statistical calculations leading to an effect size, but transformational computer use makes pre/post testing and the use of control groups very difficult. This entry has argued that many such situations can be addressed by using the concept of a curriculum-age scale. It does leave open the question of transformational learning not covered by the operational curriculum for the relevant, or indeed any other, jurisdictional area. That may be for another discussion!

Classroom Use, Blended Learning

Timos Almpanis
Kingston University, London, UK

Concepts: Definitions

Blended and hybrid learning are terms that have become increasingly popular since the beginning of the twenty-first century and they are often seen providing for the best of both worlds, incorporating elements of face-to-face and online digital learning.

According to MacDonald (2008), the blend extends beyond the combination of face-to-face and online elements to cover a blend of various technologies, e.g., synchronous and asynchronous, as well as different pedagogical approaches:

The term (blended learning) is commonly associated with the introduction of online media into a course or programme, while at the same time recognising that there is merit in retaining face-to-face contact and other traditional approaches to supporting students. It is also used where asynchronous media such as email, forums, blogs or wikis are deployed in conjunction with synchronous technologies, commonly text or audio. (MacDonald 2008, p. 2)

Beyond the concept of a simple blend, blended learning is perceived as requiring a fundamental redesign that transforms the whole approach to teaching and learning. It is not just a mixture of face-to-face and online components, but a thoughtful fusion of classroom-based and online learning experiences (Garrison and Vaughan 2008). In other words, the classroom and the online environment are fully integrated in a way that extends learning beyond the classroom, creating a continuous learning experience that makes the best uses of both environments – the classroom and the online space.

According to Allen and Seaman (2010), “blended/hybrid” courses are strictly defined as having between 30% and 79% of their content delivered online. Courses with 80% or more delivered online are named “online” while those having up to 30% delivered online are named “web facilitated” courses (Allen and Seaman 2010). This distinction may initially seem too prescriptive; however, it is useful as it highlights the spectrum of forms of course delivery.

The University of Glamorgan has adopted a similar definition of blended learning which is based on a continuum (Jones and Man Sze Lau 2010). This continuum includes the whole range of information and communication technologies (ICT)-enabled learning, from basic ICT usage to complement face-to-face teaching to fully online delivery of units/modules. Jones and Man Sze Lau (2010) underline the importance of pedagogical design in the adoption of technology, making clear that their model does not imply a simple technological add-on to existing modules, but a total redesign of the whole module/unit.

While all learning can be blended, the blend can be between various types of technology,

blending the physical with the virtual (online) environment, but also blending classroom pedagogies with the use of various technologies to enhance students’ learning. The remainder of this entry will focus on blended learning approaches in the classroom.

Classroom Technologies for Blended Learning

Classroom technologies for blended learning add interactivity in the classroom, making the student learning experience more engaging, including lecture capture software, visualizers, interactive whiteboards (IWBs), the use of mobile devices, electronic voting systems (clickers), and other online voting applications.

Separate sections will cover the following classroom technologies:

- Lecture capture technologies
- Visualizers/document cameras
- Interactive whiteboards (IWBs)
- Interactive screens
- Mobile learning – bring your own device (BYOD)
- Electronic voting systems (clickers) and online voting applications
- Augmented reality applications
- Virtual reality applications

Lecture Capture Technologies

“Lecture capture” refers to the process of recording lectures. In the past, the term was used to describe various methods of recording a session including video cameras, or even plain audio recorders. More recently, the term is used to describe software that automates the process of recording and uploading of the session to the relevant module through a virtual learning environment (VLE) or course management system (CMS).

Lecture capture software can be used for either manual and/or scheduled recordings; scheduled recordings have some implications regarding administrative workload and system integration. In many cases, only a microphone is used to record audio alongside the slides, or other desktop

applications are projected on the screen. Optionally, video input can be captured using either a mounted camera in lecture theatres (if available) or, alternatively, a plug-and-play web camera can be used with the software.

Lecture capture is used for a range of educational purposes, such as aiding students' revision, as an assistive technology, to support international students whose English is not their first language, and to improve the student experience in general. Regarding the impact of lecture capture on students' learning, while some studies have found a positive impact, findings about actual student performance are contradictory, with some studies establishing a positive impact on student grades while others report little or no impact (Joseph-Richard et al. 2018). Despite this, lecture capture seems to have a direct correlation with student satisfaction and, due to increasingly globalized and marketized tertiary education, its use has become widespread in many universities.

Some concerns have been raised about the impact of lecture capture on student attendance and it is important to emphasize that, as an educational technology, lecture capture is meant to enhance the learning experience by offering access to lectures for revision purposes rather than as a replacement for lecture attendance, which could have a detrimental effect on student attainment (Edwards and Clinton 2018).

Visualizers (Document Cameras)

Visualizers, sometimes referred to as document cameras, are the modern, digital equivalent of the old overhead projector (OHP), offering additional capabilities. A visualizer is used to project an object for the class. This can be a newspaper article, an image, or even a mobile telephone application that the teacher wants to demonstrate to the students. Other uses of the visualizer include writing or drawing on a piece of paper which is projected to the class. Visualizers can digitize anything that can be projected through them in either pictorial or video format and can also capture that projection in a digital format. Additionally, visualizers offer the option to zoom in and out, enlarging any objects that need to be studied in detail.

Interactive Whiteboards

Interactive whiteboards (IWBs) are commonly used in all educational sectors (primary, secondary, further, vocational, and tertiary). As part of a traditional setup, IWBs are connected to the teacher's computer and a projector; however, newer versions have made the projector obsolete, as they can be back-lit. IWBs are used for presentations, demonstrations, making notes, and drawings as one would do using a traditional board, or for projecting videos to the whole class.

IWBs offer a range of additional functionality including a touch screen that allows the teacher/presenter to operate the computer projected to the IWB from the IWB itself, the ability to write and draw on the screen using the IWB markers to annotate and highlight text, add notes and drawings, and then save the work and export it to either portable document format (pdf) or pictorial format. IWBs are equipped with specialist software that allows the user to write and draw tables and add shapes, images, and web links; this work can also be saved and shared. Additionally, IWBs are equipped with educational software and games for various subjects aimed at learners at different levels across primary and secondary education. Students can use the IWB individually and/or in groups to actively engage with various activities that include a range of subject-based exercises, tasks, and learning games (Barber et al. 2008) as well as use the IWB to present their work to their peers (Passey 2016).

All teacher-led and student-led work that takes place on an IWB in the classroom can be saved, exported, and subsequently it can be made available via the school's virtual learning environment (VLE) or course management system (CMS), a practice that can be beneficial to students for revision purposes (Passey 2016). IWBs can support "seamless integration and sequencing of different media," which can enable "greater fluency and pace of ideas and knowledge progression" (Passey 2016, p. 9).

Interactive Screens

Interactive screens come together with a stylus and allow the teacher to draw directly on the screen. These drawings are displayed on the interactive or static whiteboard for the students to see. Interactive screens are useful primarily in large

lecture theatres where, due to the size and height of the whiteboard, it may be impractical for the teacher to use the IWB.

Mobile Learning: Bring Your Own Device (BYOD)

Mobile learning in the classroom refers to students' access to mobile devices for learning purposes, either individually or in groups. The mobile devices are either owned by the institution or the students themselves, with the latter practice known as "bring your own device" (BYOD). The use of mobile devices in the classroom is still a contentious issue, with some arguing that access to mobile devices can assist learning (Cochrane et al. 2014) while others argue that access to mobiles in the classroom can be a distraction (Moss 2012; Ugur and Koc 2015). It is reported that the higher the students' attainment level, the more likely it is that the use of their personal devices is allowed and encouraged; while bring your own device (BYOD) policies have been implemented by some tertiary institutions (Gillies 2016), this practice of allowing personal use is rarely the case across the primary and secondary sectors where access to mobile devices in the classroom is more controlled and monitored by the school.

Mobile learning can make learning ubiquitous. Access to mobile telephones and tablets can offer expanded learning opportunities. Mobile devices are often used solely for content delivery; however, they can also be used in very innovative, interactive and even immersive ways to support creative pedagogies and collaboration. For instance, handheld devices allow students to create their own content in a variety of formats, collaborate online, and share information, becoming part of an online learning community (Cochrane et al. 2014). Some of the affordances of mobile learning when used in conjunction with other technologies are highlighted in the following sections.

Electronic Voting Systems (Clickers) and Online Voting Applications

Electronic voting systems (EVS), or classroom response systems (CRS), are handheld devices that can be used to increase student engagement with their learning. A question is projected on the

interactive whiteboard and the students can select the right answer using the handheld device (clicker). Free text input is also supported by some of these devices. However, the most commonly used question types are multiple-choice and true/false questions. The use of EVS promotes participation by everyone in the class as all students tend to respond to a question, instead of one student responding to a question when this is asked orally. Furthermore, this practice allows the teacher to see whether a question has been understood by the learners based on their responses. EVS systems have been used to facilitate more discursive, active learning approaches, including a peer instruction approach where students vote, then discuss their choice with a peer, and then vote again (Crouch and Mazur 2001).

Similar to the EVS systems, various online voting applications have been developed recently allowing participants to vote using any internet-connected devices, including laptops, tablets, and smartphones. Some of these applications allow for a wide range of questions to be asked and they can also gamify learning by timing the fastest responses, displaying images, graphics, and sounds, and listing the top winners in a series of questions based on the number of correct answers and time spent in answering them.

Augmented Reality (AR)

Augmented reality describes the process of enhancing an otherwise real environment by means of virtual objects. In other words, the augmentation refers to the process of merging the physical and the virtual environment by superimposing digital information in various formats on the physical environment, providing an immediate user interface to an electronically enhanced physical world (Schmalstieg and Hollerer 2016). Another term for AR is "mixed reality," as it allows real and virtual elements to be combined. A mobile device such as a tablet or smartphone with an AR application is used to scan the physical environment and real-world footage is viewed through the camera. Pre-recorded, computer-generated video is then overlaid in such a way that it can appear to have a location in the physical world.

AR can provide an engaging, technologically enriched learning experience to students (Hsiao

et al. 2013; Ibanez et al. 2014). Augmented reality applications can enhance a visit to a museum, for instance, by providing additional information in various formats to any of the exhibited objects or even make a book come to life by complementing it with audio or video.

Findings from a meta-analysis study (Ozdemir et al. 2018) that examined 16 studies to identify the effect of AR applications in the learning process showed that AR applications increased students' academic achievement as AR allowed them to practice what they were learning in an entertaining environment and it provided better understanding, recall, concentration, and interaction, as well as a more attractive learning environment compared with traditional learning environments.

Virtual Reality (VR)

Unlike augmented reality that merges the physical and the virtual environment, virtual reality (VR) is a simulation of a three-dimensional image or environment that can be interacted with in a seemingly real way by a person using special equipment. Virtual reality applications have been used extensively by the entertainment industry; however, they have been increasingly used for educational purposes. Using virtual reality applications, students can go on virtual field trips to museums for instance. Google has developed software that allows "field trips to virtually anywhere" (Google Expeditions 2018). The teacher can see all their students in class and use their own tablet to control their VR devices and start, pause, and stop the expedition. The teacher can also interact with the virtual environment by circling points of interest to focus the students' attention on a particular area that they want to explain. YouTube has created a VR channel which features VR videos allowing to "catch a concert a continent away or take a trip out of this world" (YouTube 360 2018).

Holoportation: The Future?

Holoportation is still considered a futuristic development, yet it might impact education in the near future. When combined with augmented reality displays, it allows participants to see and hear remote participants as if they were present in the

classroom or other physical space, creating the illusion of a natural face-to-face communication. This development may minimize transactional distance to facilitate more synchronous, visual, and human options (Themeli and Bougia 2016), blurring the boundaries of distance and face-to-face education.

Clicker Interventions: Promoting Student Activity and Feedback at University Lectures

“(..) Context is not always everything, but it colors everything” (Pajares 2005, p. 342), and in academia, the frames and contexts for teaching activities set much of the premise for how we carry out our teaching activities. What is realistic to do in small student groups can be completely unrealistic to do in large student classes. Therefore, Cleveland (2002) and Denker (2013) distinguish among “small” classrooms (30 students or fewer), “medium” classrooms (40 to 100 students), “large” classrooms (100 to 150 students), and “mega” classrooms (200 students or more). In higher education, medium or large lectures often involve less dialogue and communication between students and teachers, and several studies have found that traditional lecturing in such lectures is ineffective in promoting student learning (Deslauriers et al. 2011). Student response systems (SRSs, or “clickers”) are digital tools that can be used to increase student activity in such large lecture settings. This entry will examine how this educational technology influences “how teachers teach and students learn” in higher education today.

Lecturing is the most traditional form of teaching at universities and is still widely used, both in the everyday teaching of university students and on big occasions, when distinguished professors are invited to give guest lectures. There is an interest in oral presentation even outside the university walls, as illustrated by the popularity of TED talks, personal narratives, public lectures, and even stand-up comedy. In recent years, however, there has been increasing criticism of lectures in higher education as an outdated and ineffective method of teaching. This criticism is rooted in the increasing emphasis on student activity and student learning in education, together with an increase in students who are used to being actively included in instruction. Empirical studies support this criticism by showing that student activity and feedback promote student learning (Black and Wiliam 1998; Evans 2013; Hattie and Timperley 2007; Prince 2004) and that students struggle to maintain their attention during

lectures (Risko et al. 2012). Lecturing has also been found to be generally less effective than student-active ways of teaching in enhancing student achievement (Deslauriers et al. 2011; Hake 1998; Knight and Wood 2005; Yoder and Hochevar 2005).

Since campus-based lectures have traditionally offered little room for student activity beyond listening to the teacher talking, lecturing seems to conflict with the idea of good teaching. The primary barrier to involving students as active participants in university lectures is often the number of students present in the auditorium, which affects both the potential amount of time dedicated to each student and the students' willingness to participate due to fears of speaking in public. In these contexts, SRSs can be used to help all students present participate actively, regardless of the group size.

SRSs are digital tools that allow students to individually answer multiple-choice questions using a wireless remote control called a "clicker." The distribution of student answers can be projected on a large screen for the teacher and students to see. The student answers can also be stored for later use. Studies have found that this technology can be used to increase student activity and engagement (Boscardin and Penuel 2012; Kay and LeSage 2009; Keough 2012; Krumsvik and Ludvigsen 2012; Lantz 2010). Interventions using this technology (henceforth called "clicker interventions") can also increase student attention (Blood 2012; Cain et al. 2009; Rush et al. 2010; Sun 2014), have a positive effect on student learning (see Chien et al. 2016 for a review), and be a useful tool for providing both students and teacher feedback on the students' understanding (Egelandstad and Krumsvik 2017a, b, Forthcoming; Krumsvik 2012; Krumsvik and Ludvigsen 2012; Ludvigsen and Egelandstad 2016; Ludvigsen et al. 2015).

This entry presents how clicker interventions can be used to promote student activity and feedback at university lectures. We start by giving a historical presentation of the university lecture to highlight the functions of such lectures, the criticisms raised against them, and the challenges they face in the twenty-first century. We then present various perspectives on feedback and

how feedback situations can inform teacher instruction and enhance student learning and self-assessment. Finally, drawing on research on SRS, we present how clicker interventions can be used to promote formative feedback situations in large plenary lectures.

History of the University Lecture

In the Middle Ages, the word "lecture" (rooted in the Latin word *legere*) meant "to read aloud." At this time, a university lecture involved a teacher reading authoritative texts, most often the Bible or another ancient text, aloud to students. The number of written texts was limited. The students' job was to write down the teacher's dictation and reproduce the texts themselves. The function of the lecture was, therefore, as much about cultural preservation as knowledge distribution. For accuracy, the lecturer needed to stick to the script and could be fined for departing from the text at hand (Friesen 2011).

Following the invention of the printing press in the mid-1400s, the mass production of books began to challenge the lecturer as the sole source of information. As books gradually became cheaper and more available, students could engage in studies independent of lectures. This shift is exemplified by a young astronomy student in the fifteenth century asking: "Why should old men be preferred to their juniors now that it is possible for the young by diligent study to acquire the same knowledge" (Eisenstein 1997, p. 66).

Despite this development, the lecture maintained its original form of dictation and note-taking for quite some time. An indication of a gradual shift from pure dictation can be found in the emerging use of glosses. Explanatory notes were written into the margins of the authoritative texts to assist the lecturer in commenting on different passages, and this paved the way for the use of commentary as a way of mediating between original texts and the audience. By the middle of the seventeenth century, the two ways of lecturing – pure dictation and dictation with the use of comments – appeared to be competing for dominance. For instance, in one 1642 lecture plan,

the first half hour of each lecture was devoted to dictation, and the other half was devoted to glosses and commentary (Friesen 2011).

According to Clark (2006, p. 85), “[t]he eighteenth century appears to be the century when the dictation was first stopped.” In response to concerns over the quality of education, some governments went so far as to outlaw dictations (Friesen 2011). However, famous thinkers like Humboldt, Schleiermacher, and Fichte opposed lecturing as reading. Humboldt claimed that dictation was not suitable for engaging students and argued that teachers should create their lectures following rhetorical and didactical rules. Schleiermacher proposed that lectures should enlighten the audience with knowledge they did not previously possess and guide them toward better understandings (Skagen 2000). Thus, these and other contemporary scholars began lecturing without a set text or glossary. As Fichte (as quoted in Friesen 2011, p. 98) argued, the principal concern of a lecture is not “what is printed in books for us to read,” but, rather, “what has stirred and transformed our spirit” (p. 98). This way of thinking about understanding resonates with the hermeneutical tradition, in which text and spoken words are valuable as far as they are interpreted and brought to life as thoughts. From this perspective, a lecture should not be about the authority of books but about the lecturer using his knowledge to affect the audience. The speaker and his own words are, therefore, important. This represents a shift in the history of the lecture from the authority of the text to the authority of the teacher. Teachers as the authors of their own spoken words came to replace the medieval tradition of teachers reading the same authoritative texts (Friesen 2011).

In the twentieth century, projection media came to supplement the use of speech. The overhead projector was first used by the US military during the Second World War and was introduced in its commercial form in the 1960s. Later, this technology was replaced by similar but more advanced tools for digital projection, such as PowerPoint. Despite these changes, however, the lecture maintained its basic structure, though the dramaturgical effects of the lecture were given more attention (Friesen 2011). Goffman (1981)

distinguished among three primary modes of animation of spoken words: aloud reading, memorization, and fresh talk. In fresh talk, the lecturer improvises the text during the lecture. According to Goffman (1981), fresh talk is the ideal lecture style. With the assistance of notes, this method of lecturing is quite common, although, in reality, many lectures employ only the illusion of fresh talk. As suggested by the concept of fresh talk and fresh talk illusions, lecturing can also be considered a public performance that brings ideas and the written word into life. Hence, lecturing can provide an experience of authenticity that is livelier and more entertaining than the reading of a book on the same topic. Unfortunately, it can also be downright dull. How a lecture is perceived is likely to depend on both the performance of the teacher and the interests of the students.

This brief presentation illustrates both continuity and change in the history of the university lecture. So where does the university lecture stand in the twenty-first century?

The University Lecture in the Twenty-First Century

In the 1960s, the main criticism of lectures was rooted in the emerging criticism of authority in society. In this century, however, the focus of the criticism has instead been that lectures are ineffective in promoting student learning (Mazur 2009; Wieman 2007). Interestingly, this development marks a third shift in the history of the lecture: from the authority of the teacher to a focus on student activity and the learning outcome. An illustrative example is Biggs and Tang (2011) three levels of thinking about teaching. A teacher at Level 1 focuses on the differences among students, believing that there are good students and there are poor students. If the students do poorly, they can only blame themselves. A teacher at Level 2 focuses on what the teacher does. If the students do poorly, it is because the teacher has failed to get the message across. Finally, a teacher at Level 3 focuses on what the students do and how well the intended outcomes are achieved. If the students do poorly, it is

because the learning activities of the course are poorly adapted to promote the intended learning outcomes. From the first two perspectives, lecturing is an unproblematic way of teaching. From the third perspective, however, university lectures are problematic because they rely mostly on teacher monologue and are, thus, unfit for facilitating student activities that promote student learning.

This shift in thinking about teaching seems to be rooted in several developments. For one, the conception of how students learn has changed, such that constructivism has replaced the “transmission view” of learning as the dominating paradigm. Hence, learning is no longer understood as information that is transferred from the lecturer to the students but is “conceptualized as a process of active construction wherein learners drew on prior knowledge and experiences—both individual and sociocultural—as they built new understandings” (Cochran-Smith and Villegas 2015, p. 10). Such an understanding of learning embeds demands both for student activity and social interaction and for the teacher to assess her students’ understanding to adapt her teaching to their learning needs.

Second, there has been an increased focus on effective teaching in higher education, “understood as teaching that is oriented to and focused on students and their learning” (Devlin and Samarawickrema 2010). The global shift from an industrial economy to a knowledge economy has put greater emphasis on the importance of higher education for sustainable development and economic growth. This, in turn, has turned attention to the quality of education, particularly with respect to students’ learning outcomes (Cochran-Smith and Villegas 2015; Đonlagić and Kurtić 2016; George 2006). The number of students enrolling in higher education has also increased dramatically worldwide. This development has resulted in larger student groups, often with different cultural and socioeconomic backgrounds, enrolling in universities. Whereas the university was previously an elite institution for high-achieving and highly motivated student, teachers now must deal with more diverse student groups (Biggs and Tang 2011). Thus, lecturing and otherwise leaving students to study on their

own might serve only to replicate social differences. For this reason, the Bologna Process and National Reforms in higher education have put greater emphasis on pedagogical facilitation to even out social differences and reduce the number of students dropping out.

Third, empirical findings show that student activity and feedback situations *do* promote student learning (Black and Wiliam 1998; Evans 2013; Hattie 2009; Hattie and Timperley 2007; Prince 2004) and that student-active teaching *is* usually more effective in promoting student performance than lecturing (Deslauriers et al. 2011; Hake 1998; Hrepic et al. 2007; Knight and Wood 2005; Prince 2004; Yoder and Hochevar 2005). It has also been found that the human attention span and short-term memory are too limited to process and store most of the information contained in a long lecture (Risko et al. 2012).

In light of these developments, one could ask: Should the university lecture be kept in the twenty-first century?

The most obvious argument is that large lectures enable the instruction of many students simultaneously, which is both time- and cost-saving. Another argument presented by Tone Kvernbekk (2011) is that the monologue of the traditional lecture is less exclusive and, therefore, less excluding than dialogical approaches. She also claims that this form of education is less intrusive because the teacher cannot control whether or how the students receive the information provided. These arguments are reasonable but debatable as a defense for the campus-based lecture. The use of digital lectures and instructional designs like the “flipped classroom” offers alternatives to campus lectures that can be more cost-effective and less exclusive and intrusive, since students can, in principle, watch these videos whenever and wherever they want. Furthermore, digital lectures offer more possibilities than campus-based lectures when it comes to combining different modalities.

However, campus-based lectures do possess a potential advantage over pre-made videos with regard to flexibility and interactivity. During a lecture, students can ask questions, voice their ideas to the teacher, discuss with their peers, and reflect on both the subject and their understanding

under the guidance of an expert. The teacher can potentially improvise and make changes in her teaching based on interaction with students. Traditionally, however, student–teacher interaction has been challenging in large lecture halls with many students. Although the teacher can involve some students by posing questions to the audience, many students refrain from answering due to a fear of speaking up in public, and the few who do speak up might not represent the student group as a whole, giving the teacher a biased view of the students’ understanding.

In this context, the use of response systems has the potential to mediate the interaction between the teacher and all students present, providing valuable feedback to both the teacher and the students.

Research and Various Perspectives on Feedback

Research shows that feedback can have a considerable impact on student learning (Black and Wiliam 1998; Evans 2013; Hattie and Timperley 2007; Kluger and DeNisi 1996; Shute 2008). Feedback interventions have been found to be particularly useful when they raise students’ awareness of how to improve in relation to their current level of performance and the learning intentions (Black and Wiliam 1998, 2009; Hattie and Timperley 2007; Nicol and Macfarlane-Dick 2006; Sadler 1989). However, feedback does not always result in student improvement and may sometimes inhibit learning rather than promote it. Variations in the effects of feedback have been related to its content, form, and timing, and studies have indeed found variations based on these factors (Hattie and Timperley 2007; Kluger and DeNisi 1996; Shute 2008). For instance, the use of extrinsic rewards and praise has been found to have a limited effect on student achievement (Hattie and Gan 2011; Hattie and Timperley 2007), and extrinsic rewards can undermine internal motivation (Deci et al. 1999). On the other hand, feedback has been found to be effective when it provides information on correct (versus incorrect) responses, when it builds previous

changes, when the goals are specific and the task complexity is low, and when it is not perceived as threatening the students’ self-esteem (Hattie and Timperley 2007).

Another variation in the effectiveness of feedback is how different students perceive and use feedback (Bloxham and Campbell 2010; Carless et al. 2010; Hattie and Gan 2011; Higgins et al. 2001; Nicol and Macfarlane-Dick 2006; Sadler 2010). The literature offers numerous examples of students failing to make use of the feedback they are given (see Evans 2013; Jonsson 2013 for reviews on the topic.). This discrepancy is commonly referred to as the “feedback gap.” In a review, Jonsson (2013) found that students’ use (or lack thereof) of feedback is related to their perceptions of the information and the opportunity to use it in the near future. He also found that many students use feedback passively to motivate themselves or to indicate progress but lack strategies for employing the feedback actively. Critical feedback also seems to undermine performance and motivation when strategies for improvement are lacking (Ilgen and Davis 2000; Kluger and Van Dijk 2010). In other words, whether feedback situations have the desired effect depends not only on external conditions but also on the students’ internal conditions. Since students have different preconditions (e.g., conceptual understanding and strategies) for interpreting and using feedback, the effectiveness of feedback cannot be explained merely by its content, form, and timing; one must also consider how the feedback is received and used (Boud and Molloy 2013).

Nelson and Schunn (2009) argue that feedback has three major effects: (a) motivational, to influence beliefs and willingness to participate; (b) reinforcement, to reward and punish specific behaviors; and (c) informational, to change performance in a particular direction. Students’ experiences of feedback are likely to consist of a combination of these. It is, therefore, understandable that feedback may both support students’ learning processes and have a negative impact depending on the context, since the way in which students respond to feedback is likely to be influenced by both its emotional impact and the information it provides (Price et al. 2010).

Students differ in the ways they face difficulties and failures, and while some students may choose to respond to feedback by increasing their efforts to improve, others may become demotivated and choose to reduce their efforts or give up (Boekaerts and Corno 2005; Yorke 2003). Hence, feedback also affects and is affected by students' emotions and motivation.

Another difference in how feedback works is related to different actors' understandings of the concept. As noted by Evans (2013), the way in which feedback is conceived depends on "the particular feedback paradigm adopted" (p. 71). Different understandings of feedback lead to various feedback practices: from monologic to dialogic and from teacher-controlled to student-involved. For researchers, different understandings lead to various ways of studying these practices. The fact that practitioners, students, and researchers operate with different and often unarticulated understandings of what feedback *is* and its function highlights the need to clarify how feedback is understood. The most influential sources for conceptualizing feedback in this entry are Hattie and colleagues' (Hattie 2009; Hattie and Gan 2011; Hattie and Timperley 2007) "visible teaching and learning" perspective and the formative assessment perspective as it is presented in the most frequently cited texts in the field (Black and Wiliam 1998, 2009; Nicol and Macfarlane-Dick 2006; Sadler 1989).

Formative Feedback

The visible teaching and learning perspective (Hattie and Gan 2011; Hattie and Timperley 2007) and the formative assessment perspective (Black and Wiliam 1998, 2009; Nicol and Macfarlane-Dick 2006; Sadler 1989) are similar in their emphasis on the importance of raising students' awareness of their learning process. Hattie and Timperley (2007) focus on feedback to the students, while Black and Wiliam (2009) focus on feedback for both the students and the teacher. The purpose of feedback is to make the learning process visible to the students to support their self-monitoring and self-regulation both in the short term, when they are working with

particular tasks, and in the long term, to enhance their abilities as self-regulated learners. In particular, feedback is considered effective when it answers the questions: *Where am I going?* (feed up), *How am I going?* (feed back), and *Where to next?* (feed forward) (Hattie and Timperley 2007).

Both Black and Wiliam (2009) and Hattie and Timperley (2007) regard all situations that promote reflection as situations of formative assessment/feedback. Black and Wiliam (2009) claim that:

Practice in a classroom is formative to the extent that evidence about student achievement is elicited, interpreted, and used by teachers, learners, or their peers, to make decisions about the next steps in instruction that are likely to be better, or better founded, than the decisions they would have taken in the absence of the evidence that was elicited. (p. 9)

whereas Hattie and Timperley (2007) define feedback as:

...information provided by an agent (e.g., teacher, peer, book, parent, self, experience) regarding aspects of one's performance or understanding. A teacher or parent can provide corrective information, a peer can provide an alternative strategy, a book can provide information to clarify ideas, a parent can provide encouragement, and a learner can look up the answer to evaluate the correctness of a response. Feedback thus is a "consequence" of performance. (p. 81)

Both these definitions are quite broad, and their main difference is that Black and Wiliam (2009) focus on "evidence" that can be used by both the students and the teacher, while Hattie and Timperley (2007) focus solely on the student.

Since the definitions seem to apply to every situation that promotes reflection for the students (or teacher), what distinguishes an intentionally driven formative practice from more or less random events? According to Black and Wiliam (2009), "formative assessment is concerned with the creation of, and capitalization upon, 'moments of contingency' in instruction for the regulation of learning processes" (p. 10). In the context of education, therefore, an intended formative practice depends on the teacher facilitating situations that elicit evidence of student understanding.

Thus, the practice of formative assessment/feedback in the lecture hall depends on creating

situations in which the students can engage with the subject and receive feedback on their understanding to make more informed decisions in their studying, as well as on the teacher receiving feedback on the students' understanding in order to make informed decisions about her teaching. When feedback is conceived in this way, it is freed from a "transference" understanding of the concept, in which the teacher "tells" the students something about their performance. Instead, feedback represents the very phenomenon of the experience that arises when we act and suffer the consequences (Dewey 1997). This opens the possibility that feedback situations sometimes occur unintentionally. From such a perspective, it is the situations and the students' experiences of them that become our focus, not a message from "a sender" to "a receiver." In this context, clicker interventions can be conceived as situations in which students need to act, articulate, use their pre-understandings about various topics, and suffer the consequences of their actions, while the teacher needs to act on the feedback from the student answers and plenary discussions, which reflect on their teaching.

In this entry, we use the term "formative feedback" to distinguish between feedback as an intention or something given and feedback that becomes a learning experience. Shute (2008) introduced this term, defining formative feedback "as information communicated to the learner that is intended to modify his or her thinking and behavior for the purpose of improving learning" (p. 154). This definition differentiates between formative feedback aimed at improving learning and summative feedback for certification and control. However, to conceptualize formative feedback as an experience, not as an intention, we propose that formative feedback can be understood as a consequence of our actions; for example, just as putting your understanding into action through a discussion can reveal misunderstandings, running on the ice and breaking your leg can painfully teach you to be more careful next time. This definition also encompasses feedback that immediately enhances the students' understanding of the subject matter, not just feedback that leads to

self-assessment (metacognition). Below, we will use this understanding of feedback to present and discuss research findings on the use of clicker interventions.

Student Response Systems: Affordances and Research

A distinction can be made between SRSs operating with a designated handheld device, a "clicker," with a receiver connected to a computer, and web-based systems in which the students bring their own devices, such as smartphones, tablets, and computers. The benefit of the clicker systems is that they are easy for the students to use and usually yield a response rate close to 100%. These systems also allow the students to be sure of their anonymity when they answer if the devices are handed out at the lecture. The benefit of the web-based systems is that they are usually free to use. Furthermore, the lecturer does not have to distribute any physical devices at the lecture. An obstacle, however, is that some students cannot participate due to connectivity problems or because they do not possess a compatible device.

In large lectures, SRSs are usually employed for formative purposes to ask students subject-related questions during the lecture; however, clickers have also been used for student evaluation and summative assessment. Some of the challenges of using SRSs are that students may forget to bring or lose their remotes (when they are not handed out at the lecture), that the remotes may not function properly, that less experienced teachers may have trouble adjusting their teaching in response to student answers, that classes using SRSs may cover less course content, that creating SRS questions is time-consuming, and that students do not like when SRSs are used to monitor attendance or for summative tests (Kay and LeSage 2009).

Studies have shown that when SRSs are used for formative purposes, the students' attitudes toward the technology are generally positive. Findings also reveal that using clickers leads to increased student attendance and preparation, greater student engagement, and student

appreciation for being able to participate anonymously (Boscardin and Penuel 2012; Kay and LeSage 2009; Keough 2012; Krumsvik and Ludvigsen 2012; Lantz 2010). Studies have also found that clicker interventions increase student attention (Blood 2012; Cain et al. 2009; Rush et al. 2010; Sun 2014), and the majority of studies show that clicker interventions can have a positive effect on student learning (see Chien et al. 2016 for a review).

A common criticism of clicker studies is that they are overly oriented toward technology and lack a theoretical foundation (Beatty and Gerace 2009; Boscardin and Penuel 2012; Fies and Marshall 2006). It is reasonable to say that the theoretical underpinnings for clickers are still in their early stages and need to be developed. Instead of using “grand theories” adopted from other disciplines, it seems important to develop “home ground” theories that build on education, educational technology, and digital artifacts. This implies both theories that can explain the particular phenomenon of such educational technology use, but also analytical frameworks that hold true beyond the local setting to allow broader and more in-depth discussions of research findings outside the context of a particular study.

Although the use of digital tools offers new possibilities for instruction, it is the way in which such tools are used pedagogically – and not their use, per se – that influences students’ learning processes (Clark and Mayer 2011). This illustrates the need to distinguish between the potentials of the technology and the ways technologies can be applied. In the following section, we will present the two most common ways of using clicker interventions before reviewing research on these interventions through the lenses of formative feedback.

Clicker Interventions: The Classic and Peer Instruction Approaches

The two most common ways of conducting clicker interventions for formative purposes are what Nielsen et al. (2016) refer to as the “classic” approach and the “peer instruction” approach. The “peer instruction” approach is based on the work of Mazur (1997). Students are asked a multiple-choice question that they answer individually

before discussing their answer with the students seated next to them and re-answering the same question. In the “classic” approach, students discuss with their peers before answering individually. In both approaches, the teacher usually follows up on the student answers with a plenary discussion. Some studies have used similar interventions without peer discussions (Campbell and Mayer 2009; Mayer et al. 2009; Shapiro and Gordon 2012, 2013). After students have answered the clicker questions, a histogram of the students’ answers is usually projected on a large screen, and the teacher follows up by asking the students to explain their reasonings and providing them with her own explanations.

Clicker Interventions Through the Lenses of Formative Feedback

From clicker interventions (including the clicker questions, peer discussions, and follow-up phase), students may experience two kinds of feedback: (1) feedback supporting their self-assessment (metacognition) by raising their awareness of their understanding and (2) feedback enhancing their understanding of the subject matter. The first kind of feedback relates to studies showing that clicker interventions do raise students’ awareness of their understanding (Egelandsdal and Krumsvik 2017a). The second kind of feedback relates to studies showing that clicker interventions can also have an immediate effect on student achievement (Chien et al. 2016; Egelandsdal and Krumsvik 2017b). Clicker interventions can also provide the teacher with (3) feedback on the students’ understanding. In the next subchapters, we will use these potential “feedback outcomes” to structure and present research findings related to formative feedback from clicker interventions.

Feedback Supporting Students’ Self-Assessment

Feedback supporting the students’ self-assessment entails situations that raise the students’ awareness of their understanding. Such situations can arise from being asked a question, discussing the question with peers, and/or listening to the teacher or

other students talk during the follow-up phase. This kind of awareness can be broken down into three strands of information: *feed up*, *feed back*, and *feed forward*. Feed up denotes understanding what is essential to learn in the course (important topics, concepts, etc.). Feed back means understanding how well the students have understood the subject matter. Feed forward means understanding what the students need to focus on to improve (Black and Wiliam 2009; Hattie and Timperley 2007).

Studies have shown that creating situations that raise students' awareness of their understanding can improve student performance and help students self-regulate (Hattie and Timperley 2007), particularly when it comes to low-achieving students (Black and Wiliam 1998). As illustrated by the Dunning-Kruger effect, low competence can lead people to overestimate their abilities (Kruger and Dunning 1999), and low-achieving students tend to overestimate their understanding of subject matter (Isaacson and Fujita 2006). If students are not challenged to articulate their understanding, their self-assessment depends on seeking out and creating feedback situations on their own (Clark 2012). Since students differ in their approaches to studying, the ways in which they adapt their focus and effort will also differ (Biggs and Tang 2011; Nicol and Macfarlane-Dick 2006).

Krumsvik and Ludvigsen (2012) and Ludvigsen et al. (2015) found that clicker interventions made students more aware of their understanding (feed back). Egelandstad and Krumsvik (2017a) confirmed this finding and also found that most students experienced that, compared to lectures without clickers, the clicker interventions provided them with more information about what was important to learn in the subject (feed up), revealed misunderstandings (feed back), and showed them what they needed to study further (feed forward).

Ludvigsen et al. (2015) also found that students employed the feedback from the interventions in various ways in their coursework. Based on six interviews, they found that students used their experiences from the clicker interventions to identify difficult topics for further study, to discuss tricky concepts with one another, and to

adjust the focus of their reading. One student also claimed that the clicker interventions had transformed the way she studied, leading her to use questioning as method for self-assessing her understanding in her coursework. Egelandstad and Krumsvik (Forthcoming) also investigated whether and how students used the feedback from clicker interventions by using student logs. They found that, of their 23 participants, half (11) reported using the feedback from the interventions in their coursework, while the other half did not. Some of the students used the clicker questions as a reference point for their understanding of the course material, either by employing the clicker questions while studying or adapting their focus in light of how they assessed their understanding of the different topics. Others used the questions to engage in discussions. These students emphasized that discussing the questions afterward made them more aware of the different concepts. These approaches show that some of the students used the interventions to clarify and organize new knowledge and to self-assess their understanding. This may be particularly useful for first-year students confronted with a wide variety of concepts and theories for the first time (Nicol 2009).

Obviously, teachers cannot give students individual feedback during lectures. In such contexts, through clicker questions, peer discussions, and teacher follow-up, clicker interventions provide students with several opportunities to adjust their focus when assessing their understanding of different topics. However, reaping these benefits requires students to be able to both understand and purposefully use the information they receive. Some students may become overconfident if they answer a question correctly or be unable to use the information from the interventions purposefully. For example, in Egelandstad and Krumsvik (Forthcoming) study, only half of the students reported using the feedback in their coursework, even though most students experienced that the interventions raised their awareness of their understanding of the material and what they should focus on further. This illustrates that the teacher might need to guide students on how to consider and use information from the

interventions in their coursework and how the interventions align with course activities and learning intentions.

Feedback Enhancing Students' Understanding of the Subject Matter

The second kind of feedback concerns situations that immediately increase students' understanding of the content. Assuming that questions about key topics, reflection on these topics, discussions with peers, and listening to the perspectives of others (both students and teachers) can contribute to developing a student's content understanding, this kind of feedback can be measured by changes in student performance before and after clicker interventions.

Previous studies have found that the use of clicker questions can increase students' retention (Campbell and Mayer 2009) and that lectures using clicker questions improved students' exam performance by one-third of a grade compared to lectures without clickers and lectures without questions (Mayer et al. 2009). These findings can be related to the testing effect (Roediger and Karpicke 2006), which has shown that the use of questioning can, in itself, improve student retention. Shapiro and Gordon (2012) found that the use of clicker questions in a psychology class improved performance on delayed exam questions by 10% to 13% and concluded, based on their controlled experiment and survey, that interventions invoked the "testing effect." In another study, Shapiro and Gordon (2013) found that the use of clicker questions also promoted significantly higher performance on test questions than repetition of the same material.

With respect to the peer discussions, several studies have found that the number of students answering correctly increases when the same clicker question is re-answered after the discussion (Crouch and Mazur 2001; Mazur 1997; Rao and DiCarlo 2000; Smith et al. 2012; Smith et al. 2009; Vickrey et al. 2015). The average improvement varies between 8% and 30%. Smith et al. (2009) found that the number of students answering correctly also increases when the students are asked a new (isomorphic) question after the discussion requiring approximately the same level of

understanding as the first question, but posed as a new case. The average improvement on these isomorphic questions was 21%. In a similar study, using isomorphic questions, Egeland and Krumsvik (2017b) found an average improvement of 12% on the second question after the discussion, as well as a Cohen's *d* effect size of 0.66. This is 65% above the average effect of interventions aimed to increase student performance, which is 0.4 (Hattie 2009). These studies show not only that the students improved on the initial question they discussed but also that the knowledge they gained transferred to a new case.

Some studies have also found that the combination of peer discussions and teacher follow-up can enhance student performance even more (Smith et al. 2011; Zingaro and Porter 2014).

Feedback to the Teacher

There is a considerable difference between teachers' and students' understandings of various lecture topics (Hrepić et al. 2007). This makes it hard for teachers to assess how students receive the material presented. This is a challenge for the teacher because the students' pre-understanding has a significant impact on how a lecture is experienced (Schwartz and Bransford 1998). One of the benefits of using clickers is that a teacher can quickly collect answers from all students present. Although studies have shown that clicker results can sometimes misrepresent some students' understanding (James and Willoughby 2011; Knight et al. 2015; Wood et al. 2014), the interventions do provide the teacher with a general idea of how well the students have understood the material (Anderson et al. 2011; D'Inverno et al. 2003; Kolikant et al. 2010). This feedback can be used synchronously to address the students' understanding and misconceptions in the follow-up phase (Kolikant et al. 2010) and asynchronously to adapt future lectures and the amount of time spent on various topics to the students' needs and current levels of understanding (Anderson et al. 2011; D'Inverno et al. 2003).

The teacher must, however, be aware that there are several nuances not captured by clicker answers (James and Willoughby 2011). Since clicker questions are multiple-choice, both the

questions and the answers need to be constructed by the teacher; thus, they might not accurately represent students' own questions and ideas. It is, therefore, crucial for the teacher to follow up on the students' answers at the end of the interventions to ask them to explain their reasoning or to use a digital tool (e.g., Flinga) to enable the students to write their comments, answers, and questions freely.

Negative remarks from teachers concerning clicker interventions are usually related to a loss of lecturing time (Egelandsdal and Krumsvik *Forthcoming*). This illustrates the major trade-off when using clicker interventions, namely, that there will be less time for lecturing. If the teachers experience, however, that they are "teaching more by lecturing less" (Knight and Wood 2005), this trade-off might be well worth it. As illustrated in many studies, the amount of material covered does not equal the amount of material learned (Deslauriers et al. 2011; Hake 1998; Hrepic et al. 2007; Jennifer K. Knight and Wood 2005; Yoder and Hochevar 2005). As noted by one of the teachers in Egelandsdal and Krumsvik (*Forthcoming*) study, it is better to focus on a few important points than to provide students with a great deal of information that they do not retain. Since humans have limited short-term memory and attention spans when it comes to retaining information from lectures (Risko et al. 2012) and clicker interventions increase student attention (Blood 2012; Cain et al. 2009; Rush et al. 2010; Sun 2014), this is a valid point in itself. Studies have also found that brief activities help students remember more content (Prince 2004), that the use of clicker questions enhances student retention (Campbell and Mayer 2009; Mayer et al. 2009; Shapiro and Gordon 2012, 2013), and that students are likely to understand more of the content if it is simple, explicitly stated, and reiterated multiple times (Hrepic et al. 2007). Hence, reducing the amount of material covered, slowing down the tempo, and using questions and peer discussions might be acceptable from a "student learning" point of view.

The ways in which teachers use SRSs depend on the possibilities they identify, both with respect to the affordances of the technology and the

pedagogical opportunities to facilitate purposeful activities. How these activities play out might also be affected by unintended events and consequences (Kirschner et al. 2004). Studies have found that the perceived advantages of clicker interventions increase when teachers become more experienced with using them (Draper and Brown 2004; Kolikant et al. 2010). In this respect, it is important for teachers to be aware that becoming familiar with the technology, creating appropriate questions, and learning how to adjust their teaching based on information from clicker interventions are likely to be a process of development (Boscardin and Penuel 2012).

Conclusion and Suggestions for Practice

In this entry, we have seen that clicker interventions can be used to promote formative feedback and student activity in university lectures. Clicker interventions can be used to engage students in peer discussions and gather answers from all students present, and they also serve as a catalyst for plenary discussions. A benefit of clicker interventions is that they allow the teacher to collect answers from the whole student group instantly, usually yielding a response rate close to 100%. They also work well regardless of group size. Clicker interventions can inform teachers and students about the students' current understanding and can be used to adjust studying and teaching. As we have seen, clicker interventions can also have a positive impact on student learning, motivation, attention, and engagement.

A limitation is that both the questions and answers in clicker interventions need to be pre-constructed by the teacher, since they are multiple-choice. It is particularly important that the teacher pay attention to the purpose of the lecture when constructing the questions. A recent study found that the use of solely factual questions can improve student retention, but simultaneously impede conceptual understanding because they can orient students too heavily toward facts (Shapiro et al. 2017). Even in a multiple-choice system, it is still possible to construct questions to which the answers are not merely "right" or

“wrong” by, for instance, using questions for which the alternative answers represent different perspectives on a topic. It is also possible to construct questions that require a deeper understanding, such as case questions that the students must use their understanding of the subject matter to solve. The clicker questions can also be used in combination with modalities other than text and speech. For example, in studies by Ludvigsen et al. (2015) and Egelandstad and Krumsvik (2017a), the lecturer used a combination of clicker questions and video cases. In these cases, the students needed to employ their understanding of the subject matter to interpret and solve the cases presented to them. Professor Rune J. Krumsvik, who has used clickers systematically in large lectures for psychology students since 2008, states that “[t]he combination of such educational technology, peer discussion, authentic video cases from the practice field and feedback as theoretical underpinning, have increased the interactivity and the student engagement, and changed the teachers’ and students’ roles.”

To explore students’ own ideas beyond plenary discussions, it is also possible to collect answers to open-ended questions or allow students to submit their own questions before the lecture for use in the planning of clicker interventions. Another option is to combine the use of clicker interventions with a qualitative response system, such as Flinga. These systems allow students to write text-based answers on a shared digital wall, thereby allowing students to submit explanations for their clicker answers.

Although the kind of questions used is important and different kinds of questions serve different purposes, another essential factor in clicker interventions is the level of facilitated interactivity. If response systems are used in combination with peer discussions and the teacher follows up on the student answers and uses them purposefully to make changes in her lecture, the change from a traditional lecture will be more extensive than if a teacher merely poses a few questions and then moves on with the monologue. The quality of the interventions also rests upon how well the teacher follows up on the students’ answers. For example, a teacher might simply collect the

student answers and not engage them in a discussion of different perspectives or, alternatively, relate the ideas to one another, compare and contrast them, and relate them to existing ideas discussed in the course. This second approach uses information from clicker interventions to create tension between the ideas of the students and the ideas of the discipline, which can allow the students to draw connections between their everyday views and the ideas of the course and to become more aware of the different perspectives on a topic.

Similar terms: challenges for social media users and society, dilemmas of social media influence, public discourses on social media impacts, social media as public good, current status and future direction of social media

Social network as medium is a great tool for collaboration among individuals without geographical and synchronous communication barriers. Tools such as Google drive or Facebook allow users to collaborate with multiple individuals not only without geographical distances but also without necessary synchronicity, i.e., people can edit shared files in a cloud server any time anywhere in the world without disrupting the work flow from anywhere in the world. One of the benefits of working on shared files is the efficiency gained through modularization and granulation (Benkler 2007). Massive size data files can be modularized into small fractions and divided among multiple individuals. This way, the workload can become manageable for an individual. A good example of modularization is provided in Benkler (2007). Activist students at Swarthmore College tackled a massive

amount of email exchanges among the employees of Diebold, a voting machine manufacturer, about the defects in their products, by dividing the work through modularization. The modularization has a powerful impact on data processing by allowing individuals with a clear objective to produce and share the outcomes of their work among themselves or with the public. The recent case of Panama Papers is another example of high-profile social network collaboration. Analyzing the massive amount of documents that eventually became known as Panama Papers (see Harding 2016) was an almost impossible task for an institution, let alone an individual. Also, the work required an unprecedented amount of resources and coordination among experts such as journalists, data scientists, and linguists because the information had to be deciphered by experts and the vast amount of data had to be processed before to be usable. The International Consortium of Investigative Journalists (ICIJ), a multinational alliance of professional journalists, took on the task. ICIJ modularized, granulated, analyzed, and, in the end, reported through the outlets of each journalist's institution. Indeed, this type of work is not just in the areas of the social activism or journalistic work. The advantages of collaboration network are very clear in the current work environment where various social network communication methods such as email, social media, texting, and cloud server elevated the efficiency of communication among the employees of many organizations around the world.

Identities, Trust, and Social Cues

Highly productive collaboration networks share one characteristic that the average social networks often do not have. The identities of the participants are known or recognized among the participating members, at least through pseudonyms. In other words, some level of trust is built in their communication through the known or recognized identities. It is difficult to imagine that the online collaborators would have analyzed and published highly sensitive and controversial information such as the Panama Papers or Diebold email

exchanges without trusting other participants because they had to maintain secure and private in-group communications.

Unfortunately, deception is regular part of social media user experience (Donath 1998). Because social media users often do not know who is on the other side of the screen, it is difficult to build trust with the people they are communicating with. When present, deception can erode trust among the participants of a social media and potentially damage the quality of interactions among individuals online.

In a typical offline situation, social presence of a communicating counterpart is an important element that can foster trust among the participants. As people learn to communicate with others as part of human development, they use the physical presence of others as non-textual clues. The social presence cues provided during face-to-face communication are critical for functional communication exchanges. Demographic information, facial expressions, gestures, voice tones, and many other cues are taken into consideration as people put together their responses in their interaction with others. In text-based online communication, however, many of these cues are absent and only a limited number of cues such as usernames or Internet Protocol (IP) addresses are available (Wood and Smith 2005). This presents a challenge to social media users because the lack of social presence of their communication partners leaves them with only limited cues to use and thus substantially curtails applicability of their offline communication skills.

Still, consciously or unconsciously, social media users use whatever cues they can grasp during online interactions and thus, at times, they can be overly dependent on a small number of cues that they can detect. Easily identifiable among them are writing style, inadvertently disclosed information in texts, IP addresses revealed through site interface, and several others. For instance, social media users can take note of a gender cue in a username (e.g., XenaTheWarrior-Princess) and heavily base their interaction with the owner of the username and the person's posts on the gender cue. Especially if the gender cue is the only social cue that the social media users find

in the posts, they are more likely to use this cue, i.e., female gender, excessively. Furthermore, if the communication exchanges are not satisfactory, they may make disparaging comments about the owner of the username based on sexism. Social context cues theory (Wood and Smith 2005) explains that the heavy dependence on the gender cue can disproportionately influence the way online social network users communicate with one another because no other cues are present and people tend to use any cue that they can find in their communication.

Cooperation Rules and Medium Structure

The (over)use of limited cues that we find during online communication is problematic because the cues, or perceived traits of other users, can introduce social stereotypes into the communication and thus lower the quality of interaction. Combined with the anonymous nature of social interactions online, online social networks can easily become "online cesspools" of our nasty desires (Herbeck 2013). Some researchers proposed that one way to avoid unproductive interactions on online social networks is to enact cooperation rules based on known identities, ongoing relationships, and information about other participants (Kollok 1998). One's history of interactions with other users can offer plenty of information about the user's online behavior and thus having the history available for all participants could make online social network participants more mindful about their manners. On online social networks, however, many of these measures are difficult to implement. For example, users access online social networks from all around the world and each country has its own rules regulating social media participation. In most western countries, there is no mandatory real ID policy or mandatory history archiving (e.g., no history function on Snapchat) for online communication participation because of its legal implications and logistical challenges. Social media sites do have their own legal parameters, but the enforceability is highly limited. For example, Facebook's legal

agreement allows real identity only, but it is almost impossible to enforce real identity during the user sign-up process.

The good news is that the majority of Facebook users, 92%, use their real identities when registering on Facebook (Madden et al. 2013). Maybe, Facebook is special in terms of the number of real identity users because most individual accounts on Facebook, except Facebook “Pages,” utilize existing social network and the site is primarily used for closed network communication where only approved friends in the network can view and interact with one another. Users of such closed-system networks (e.g., Facebook, Instagram, Snapchat, etc.) can enjoy the advantages of interacting with known identities and having informative user interaction history available to them. On the other hand, many other online social networks do not use the closed-network system. Twitter is a good example, although Twitter also has a closed system function that is less utilized by its users. Because Twitter is originally built for the users who want to disperse their ideas by using an open-network system, Twitter posts, a.k.a. Tweets, are accessible to anyone on the network even the users do not have the following or follower relationships (e.g., through hashtags). On top of that, the followers can also take a peek at any public information of a Twitter user.

The openness of different social network services can be classified into three categories: private-micro, semi-private-meso, and public-macro (as defined in Bruns and Moe 2014). The different levels of network openness, in turn, have implications for the exchange of information. Private networks can be used for closed communication with other people who shares similar interest and the examples could include the ICIJ journalists in the Panama Papers scandal and Swarthmore College students in the Diebold case. As illustrated in the cases, people who are geographically dispersed can get together and talk about the topics that they feel passionate about. Because private, micro-level online social networks are more likely to be trusted by their users, the networks can be more effective in facilitating the exchange of ideas and efficient collaborations. Indeed, the advantages of private communication

networks have been well utilized among social media users, sometimes at the peril of the well-being of the society. The private nature of some social networks that allows their users to evade the scrutiny of authorities have facilitated exchanges of ideas that are viewed as socially undesirable or even extreme.

Balkanization and Filter Bubbles

Various types of information have been shared among the members of private social media groups to persuade other members to share some of the group members’ extreme views and further instigate them to take destructive actions against those who do not share the views. The reinforcing nature of in-group communication in private networks allows extreme ideas to take hold and flourish within the community (Sunstein 2009). When the members of a closed private network communicate with one another and keep reinforcing their shared view by exposing themselves only to the information that is consonant with the established view, the extremely one-sided view will become prevalent in in-group online social networks on both ends of the political spectrum, whether left or right. It is difficult to examine private groups’ communication because of the closed nature of their networks. However, even communication in meso- or macro-level public networks such as Twitter show extreme polarization of ideas on politically charged topics (e.g., Smith et al. 2014). The psychological mechanisms of such polarization have been explored by social media researchers as well (e.g., Yun and Park 2011). While we can tout the collaborations among people in a closed network environment to solve problems or advance knowledge and understanding, divided public armed with one-sided extreme ideologies cannot be beneficial for the collective society because a democracy requires compromises among its members who can put public interest over their own ideologies. Unfortunately, it is difficult to deny the divisive role that in-group communication on social media has played in contemporary politics all around the world.

Filtering, a heavily utilized technological innovation, is also contributing to the polarization. Google search engine had revolutionized internet search by prioritizing network centrality such as closeness and eigenvector centrality in ranking search results. In deciding which results should be ranked higher than others, the algorithm tabulated inner edge networks based on the number of hyperlinks from other webpages (Barabasi 2003). Subsequently, the technology evolved into tailoring and personalizing information for individual internet users. Highly personal and relevant information that also matches users' personal taste is now selected, sorted, and prioritized for individuals. Constantly evolving search engine algorithm and business deals that allow companies to share consumer information (e.g., shared beacon information between advertisers and content providers of Facebook, see Schonfeld 2007) is further fine-tuning the technique. Because personalized information is often pushed to the devices used by each individual, people conveniently access pre-selected and superbly tailored information from their device interface with a minimal effort. This personalization is quite convenient and efficient. But, we may be paying the price for the convenience by creating further social and political division among ourselves.

The issue here is not just the static polarization, but the acceleration of the polarization. The filtering and personalization potentially create invisible information bubbles in which individuals are exposed only to the information that fits in their existing political beliefs, i.e., filter bubbles (Pariser 2011). Because contemporary news consumers are increasingly more likely to rely on social media, filter bubbles can pose a serious threat to the cross-pollination of information and perspectives, which is crucial in drawing a consensus among opposing parties in a democratic society. In other words, people may rely less on public information sources such as mainstream newspapers and network television news that are typically less tailored and more broad-based. At the same time, they could consume more of micro-level, precisely tailored information that further pushes already one-sided views of individuals to the edges of the shared social values and norms. In addition, serendipitous exposure to some

information that could lead to a discovery of a new perspective or bridging between opposing views is less likely to happen due to the filter bubbles.

Old and New Hope of Facilitating Engagement: Recommendation/Reputation and Fiero

While there is substantial evidence supporting balkanization and filter bubbles as the outcomes of online collaboration, some researchers have approached online collaboration from quite a different perspective. They have taken a social engineering approach and tried to change the outcomes of online collaboration through new interface design features and/or collaboration mechanisms. One of the engineering innovations is recommendation/reputation systems. Recommendation/reputation systems have been around since the idea of exchanging ideas and goods via online social network began to emerge. In spite of the concerns raised in the early days of the network economy, the online marketplace of ideas and goods, for the most part, have not suffered from the problem of market for lemons where cheap and low-quality goods flood the market and eventually destroy the market. Online marketplaces like Ebay.com and Amazon.com are good examples and their success is often credited to the trust among the participants largely based on the recommendation/reputation system. Without the product reviews or vendor ratings that are now almost ubiquitous on e-commerce websites, it would have been very difficult to build trust between sellers and buyers. It would have been also very slow to initiate, sustain, and diffuse the transactions through the networks. Similarly, quality ratings, including information sharing, of the stories and opinions of others in media outlets have been helping content consumers' decisions such as spending time reading the recommended articles and placing how much trust in the information or perspective in them. The comments posted by many other readers can provide a general sense of the climate of public opinion, rather than reaffirmation of in-group opinions in filter bubbles, and expose news consumers to what

other people think about a give topic. The recommendation/reputation system may be able to counter extreme polarization and even facilitate better collaboration between suppliers, whether information or products, and consumers.

Another group of researchers go even further to engineer collaborations amongst online social network participants through games. McGonigal (2011) suggested that social network games can be beneficial to our mental health, if used and enjoyed properly. She argues that the punitive approaches to video games that focus on negative effects such as violence, social isolation, and mental health need to be revisited. Instead, she maintains, human connections provided through network video games can lead to happiness, because video games can teach us how to achieve goals through collaborations with others by using the gamification method. Because accomplishing a challenging, but achievable, goal through collaborations often provides ultimate euphoric feelings that can be harnessed during game plays, a.k.a. *fiero*, properly gamified network systems can facilitate and motivate productive collaborations among the participants. McGonigal (2011) argues that gamified online networked environment can incentivize individuals through the expectation of experiencing *fiero*. In fact, the two aforementioned examples, Diebold email exchange and Panama Paper cases, contain an element of emotional gratification. They probably experienced *fiero* when they made progress and ultimately completed the assigned modularized and granularized tasks, meeting their collective goals. This collaborative work process to achieve shared goals provides a great sense of shared joy, and it can be a priceless experience, particularly when the completed results made big impact on our global discourses.

Conclusion

Online network collaboration has grown tremendously during recent decades. Although there have been many excellent examples of what network participants can accomplish through the collaboration, its unfortunate drawbacks have also manifested in various forms including but not

limited to extremism, polarization, fear of missing out (FOMO), revenge porn, doxing, and anxiety and depression caused by social comparison. None of these problems are easy to solve because all of them are intrinsically intertwined with many aspects of social and psychological fabrics of our lives. However, it is ill-advised to give up on the positive potentials of online social networks, given the proven benefits and widespread use. Instead, it would be more productive to adopt the social engineering approach and constantly improve the communication networks to bring about positive outcomes to individuals and their society. Proper implementations of reputation/recommendation systems can enable online social network users to distinguish between high- and poor-quality information. By setting good rules, procedures, and goals, we can also help the participants of online collaboration projects experience positive feelings, like *fiero*. Online social network collaboration is still in its early stage and has much potential. More creative ideas, or cocktailing those creative ideas, countering the negative aspects of online collaboration should be developed and distributed to overcome the challenges of the current online social networks.

Collaborative knowledge building; Group learning; Social constructivism; Team learning

Introduction

Collaborative learning is an educational approach that involves two or more people who learn while working together on a joint task in order to achieve a common goal (e.g., to solve a problem or to design a product) (Dillenbourg 1999a). Collaborative learning builds on the idea that learning is a social activity which takes place when learners interact with their social environment (Vygotsky 1978). It is a research field with a long history that spans multiple disciplines such as sociology, psychology, and learning sciences. Early studies on collaborative learning go back to the 1920s (Allport 1924).

Research in collaborative learning explores the way learning occurs when two or more individuals work together in order to achieve a common goal. In particular, collaborative learning studies:

- The mechanisms that are activated when people communicate and collaborate
- The means to scaffold meaningful interactions between peers that may lead to learning
- The practices that facilitate collaborative learning to improve the learning outcome both from the learners' and the teachers' perspectives.

On a practical level, collaborative learning approaches are commonly adopted and illustrated in classrooms when students are asked to work in groups and deliver a common assignment.

When people collaborate in a social context, meaningful interactions may occur under certain circumstances which will trigger learning mechanisms and eventually lead to learning. However, it cannot be guaranteed that these desired interactions will indeed take place and that they will result in learning. Research has shown that social interaction between students can potentially improve learning and that students benefit more when working with peers (Crook 1994; Fawcett and Garton 2005; Roschelle and Teasley 1995; Slavin 1992; Stahl et al. 2006). To that end, numerous pedagogical methods have been proposed to promote and to scaffold interactions among peers with the premise that these interactions will lead to learning in a social context (Brown et al. 1989; Cobb 1994; Valsiner and Van der Veer 2000).

In recent years, technological advances have led to the use of computers to support collaborative learning either in classroom settings or in online learning contexts. This newly emerged research area is known as computer-supported collaborative learning (CSCL), and it studies how computer-mediated collaboration can scaffold learning (Stahl et al. 2006). On the one hand, using technology to facilitate collaborative activities makes collaboration easier on a practical level. Students have access to common resources, they can share material with the learning community, students' activities can be logged for post-analysis purposes, and, most importantly, students can participate from anywhere and at any time (Crook 1998). On the other hand, the use of technology contributes to improving learning by scaffolding argumentation, fostering co-construction of knowledge, as well as supporting coordination of peers. Additionally, collaboration contributes to shaping the students' behaviors who, in a social context, do not act as individuals but as the members of a team who work together toward a common goal (Scardamalia and Bereiter 1991; Stahl 2005).

In this entry, an overview of the background, the research approaches, and the patterns of practice in the field of collaborative learning are provided. A definition of collaborative learning and an overview of fundamental aspects that shape research and practice in this field are included. Pedagogies and learning theories that are used as foundations of the field alongside goals and objectives of collaborative learning approaches are discussed. Popular patterns of practice, exploring their application in classrooms, and elaborating on the state of the art around those practices in research are outlined. A discussion about important topics, open questions, and future directions are provided in conclusion.

Background

Definition and Fundamental Aspects of Collaborative Learning

Collaborative learning is commonly considered part of the learning sciences. However, it is an

inherently interdisciplinary field that provides a common ground for other research disciplines such as sociology, computer science, and cognitive psychology (Dillenbourg et al. 1996; Hmelo-Silver 2006). Collaborative learning studies the learning mechanisms that come into play when people collaborate to reach a common goal. It also studies the means to support people who share or build common knowledge and eventually how to improve the learning process and its outcomes. However, describing collaborative learning using one definition is challenging due to the complexity of the field (Dillenbourg 1999b) and because it takes place in a wide context (usually wider than a classroom). It involves everyday practices of people who interact within a social arena in which learning occurs under specific circumstances (Lave and Wenger 1991). Vygotsky discussed the role of the social context with respect to learning through his theoretical approach that identified the zone of proximal development (ZPD). The ZPD can be defined as “the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers” (Vygotsky 1978). This definition of the ZPD highlights the importance of collaboration and social interaction when it comes to learning.

Collaboration, as an activity, is described by three dimensions that impact the way we design, implement, and carry out collaborative learning activities as well as how we choose means to facilitate them. These dimensions are:

1. *Time*. Synchronous activities – that is, activities that require synchronous communication between learners – usually unfold over short period of times (e.g., a few hours), and students communicate over voice channels, face-to-face when co-located, or instant messaging. Asynchronous activities – that is, activities that do not require synchronous communication between learners – can take place over longer periods of time, and students usually communicate via emails or written texts.

2. *Location.* Typically, collaboration is perceived as a co-located activity. That is, people who work together are expected to physically share the same space. This is not necessarily the case in collaborative learning since the use of technology can provide means for people to collaborate efficiently that are co-located as well as people that are not. In the case of co-located collaboration – for example, face-to-face meetings – technology can provide resources or assistance to support students to interact or to coordinate. In the case of distant collaboration, technology can additionally provide a virtual, common space for people to interact and communicate and thus bridge the gap created by distance.
3. *Group size.* The size of the group in collaborative contexts (i.e., the number of people who work together) can vary from dyads (pairs) and small teams to classroom size (20–30 students) or larger (social) groups like, for example, massive open online courses (MOOCs) or communities of practice.

Several theoretical and methodological frameworks take these dimensions into account when designing and analyzing learning activities (Dillenbourg 1999b; El Helou 2010; Kirschner and Erkens 2013; Pozzi and Persico 2011). There are also approaches that focus on exploring the impact and significance of the aforementioned dimensions on collaborative learning or study-specific phenomena that can be traced back and attributed to these three dimensions (Antunes et al. 2012; Reimann 2009).

Early research in collaborative learning focused on the group level: the interactions between group members, the means (technological or others) that facilitate collaboration, and the effectiveness of these means on collaborative practice. Later on, the research field expanded to include work from closely related fields such as informal learning, game-based learning, educational data mining, and teacher education.

Pedagogies and Learning Theories

In principle, collaborative learning can be considered a constructivist approach that focuses on

the interaction between people (Suthers 2012). As such, it builds on the principles of *constructivism* and *social constructivism*.

Constructivism (Doise et al. 1984; Piaget 1928) emphasizes the way humans develop in relation to their experiences. Similarly, social constructivism (Vygotsky 1980) focuses on how humans learn by interacting with others in a social context. Social interactions can expose people to divergent views and require them to familiarize themselves with new ideas and experiences. In a social arena, humans are expected to be able to elaborate on their own views and perceptions and to externalize knowledge. To enable these interactions and potentially turn them into learning experiences, learners have to establish a common ground which allows them to exchange information and share and build knowledge. In this sense, learning is not just the end goal (or the outcome of a collaborative activity), but it describes the whole process of working with others in a social context and toward a common goal.

The increasing popularity of the field that came along with technological advances in computer science has led to the adaptation of constructivist pedagogical approaches in order to address the specific needs of collaborative learning. Examples of popular theoretical trends in collaborative learning include the theories of *collaborative knowledge building* (Scardamalia and Bereiter 1991), *group cognition* (Stahl 2005), *knowledge-creating organizations* (Nonaka and Takeuchi 1995), and *construction of shared meaning* (Bell et al. 2002).

Research Methodologies

Research methodologies in collaborative learning can generally be classified as *quantitative* or *qualitative*. However, in recent years, there has been an effort to move to mixed methods approaches that involve triangulation between different methodologies.

Quantitative approaches aim to examine the relationship (if any) between factors, to assess the impact of independent variables on dependent variables, and to detect causal relationships. In collaborative learning, a typical dependent variable is the learning outcome, as assessed by

pre- and post-knowledge tests or with respect to the successful outcome of a learning activity. Quantitative approaches are typically *systemic*, in the sense that they involve the use of computational models to model the relationship between quantifiable variables or features and their effect on the collaborative learning process (Greeno and Engeström 2006). Quantitative methodologies include descriptive research, explanatory methods, and experimentation (Johnson 2001).

Qualitative approaches are usually *descriptive* and/or *dialogic*. Such approaches involve field observations of processes or phenomena and their unfolding over time in a specific context, and they focus on the analysis of verbal (or written) interaction between peers to understand the ways people work together (Valsiner and Van der Veer 2000). Qualitative methods used in collaborative learning research typically derive from ethnology, ethnomethodology, discourse analysis, and grounded theory (Lipponen 2002).

Goals and Objectives

The main objective of collaborative learning is to improve the learning outcomes. This objective can be broken down into subgoals that may contribute to improve students' performance, such as to improve the quality of collaboration, to scaffold students' motivation, and to foster creativity.

Thus, research in the field of collaborative learning extends toward several subfields (Lehtinen et al. 1999; Lipponen 2002). It can, however, be grouped into two main categories:

1. Studying *new pedagogical methods* and practices that aim to improve learning
2. Exploring, mapping, and understanding the underlying *collaborative mechanisms* and the factors that affect the outcome of a collaborative activity

The aforementioned categories are neither mutually exclusive nor independent. On the contrary, research usually intertwines both categories. Furthermore, it is important to ensure the effective integration of technological affordances and pedagogical interventions into the learning

design. Therefore, there is a great need for analytical and evaluative approaches in order to inform research and practice. However, analytical and evaluative approaches as well as research regarding learning design are beyond the scope of this entry.

Research Practices in Collaborative Learning

Collaborative learning includes a wide variety of learning activities that range from collaborative problem-solving, argumentation, and project-based activities to game-based or online learning. In this section, an overview of collaborative practices that aim to scaffold learning in a classroom setting is provided. In particular, work practices that stem from the following collaborative learning approaches are presented:

- Collaborative learning over shared artifacts and representations
- Project-based learning
- Game-based learning
- Collaborative learning scripts

These work practices are not necessarily collaborative, in the sense that they can also facilitate individual learning. However, in this entry, these practices are explored as collaborative approaches. Furthermore, these approaches are not necessarily exclusive, but they can be combined to accommodate different learning contexts and goals. For example, it is an established practice to combine collaborative scripts with the co-construction and use of shared representations in order to teach argumentation (Scheuer et al. 2014).

In this section, practices that are usually applied in classrooms have been included. Other popular approaches, such as online communities and MOOCs, are not discussed here. Nonetheless, the reader should keep in mind that the purpose of this entry is to inform about common collaborative practices and recent advances. It is not an exhaustive overview of all existing literature on collaborative learning practices.

Collaborative Learning Over Shared Artifacts and Representations

A *learning artifact* can be any object created by students during a learning activity that can provide “*evidence*” of the learning process (Kafai and Resnick 1996). The collaborative construction of artifacts is a typical activity that can promote learning, elicit reflection, and facilitate communication between peers. In this case, the learning artifact is the outcome of a collaborative process, and as such it reflects the quality of collaboration as well as the potential learning gains of the collaborators (Hoppe 2009). Collaboration over shared artifacts can facilitate collaborative knowledge building by promoting the transition from tacit knowledge (i.e., internalized knowledge that is difficult to communicate to peers verbally or in written form) to explicit knowledge (i.e., formal and concrete knowledge that the learner can communicate to peers) through externalization but also to support reflection by transforming explicit to tacit knowledge through internalization (Nonaka and Takeuchi 1995).

Examples of learning artifacts commonly used in classroom settings are diagrammatic representations – such as algorithmic flowcharts, concept maps, and argumentation diagrams – but also co-written reports, bricolages, or even collaborative portfolios that represent the work of a student group over time. We will explore examples of learning artifacts through a range of research studies in the remaining paragraphs in this section.

Suthers (2005) and Suthers and Hundhausen (2003) studied the use of collaboratively created artifacts, such as graphical representations of hypothesis and relations. They found indications that the use of shared graphical representations can positively influence collaborative learning by enabling communication and stimulating discussion and co-construction of knowledge. Analysis of collaborative learning activities showed that students interact with and through the artifact in a similar way as they would during a discussion. This interaction over a shared artifact enables argumentation and supports participants in reaching an agreement. It was also suggested that the criteria for supporting

participants’ grounding and knowledge co-construction were present in such a setting (Suthers 2005).

Concept maps (i.e., diagrammatic representations that map the relationships between concepts) have been widely used in collaborative learning. Research has shown that the use of concept maps as a collaborative tool promotes the externalization of knowledge (Hoppe and Gassner 2002) and fosters critical thinking and active learning (Daley et al. 2016; Kinchin et al. 2008). Manske and Hoppe (2016) explored the use of concept maps on a meta-level, to inform students and teachers about the progress of collaborative knowledge construction and to scaffold reflection. To that end, they built structured visual representations of semantic concepts based on a model of (shared) student knowledge. The authors experimentally demonstrated how visual representations of collaborative knowledge building can support learners and teach them epistemic fluency.

Collaborative construction of argument diagrams has been shown to be beneficial, in particular, for learning to argue and to co-construct knowledge (Chounta et al. 2017b; Scheuer et al. 2014). Schwarz and De Groot (2007) used graphic tools to promote critical reasoning for argumentation during a history class. Their findings suggest that the co-construction of shared representations benefits students with respect to coherence, decisiveness, and openness.

Voyiatzaki et al. (2004) studied the case of teaching algorithms through peer collaboration over co-construction of diagrammatic representations (graphs) in secondary school classrooms. To facilitate the collaborative building of graphs, the authors used a computer-based environment adapted for the needs of 15-year-old students with minimum computer-related experience. According to the authors, the students were able to adapt to the needs imposed by the setting, they collaborated without difficulties, and the use of technology did not negatively influence the students’ activity. The authors reported no significant learning gains but pointed out important issues that related to resource allocation that should be taken into account when designing collaborative activities for school classrooms.

Kahrimanis et al. (2009, 2011) studied the collaborative creation of algorithmic flowcharts in the classroom for teaching a first-year university course on “Introductions to Algorithms.” Their results indicated that the produced artifacts (i.e., the collaboratively created flowcharts) can capture and reflect the quality of collaboration between peers and they can be used as a post-assessment tool for teachers and researchers.

Collaborative Project-Based Learning

Collaborative project-based learning (PBL) is an educational approach that aims at teaching students by engaging them in pursuing solutions to problems through investigation (Thomas 2000). Learning activities are driven by projects that the students carry out collaboratively in teams. During the process of working together on a common project that reflects the knowledge and skill of the group, the students learn on an individual level through inquiry and self-reflection and on a group level through researching and creating artifacts along with their peers for the purpose of the project.

The outcome of a project is usually a product that addresses the learning objective (Blumenfeld et al. 1991). Typically, the students have to engage in various design, problem-solving, and management tasks while they interact with their peers to successfully complete the assigned project (Thomas 2000). The learning outcome of a project-based learning activity cannot be predetermined. Therefore, students and teachers have to continuously monitor, evaluate, and improve their practice in order to achieve the desirable learning outcome (Barron et al. 1998). Thus, project-based learning is considered an innovative and promising approach for fostering important skills for the twenty-first-century learner, such as critical thinking, collaboration, and creativity (Bell 2010; Chounta et al. 2017a).

Schneider et al. (2002) adopted the idea of project-based learning for web-based educational approaches. In such approaches, the teacher neither instructs nor teaches students actively. The teacher rather encourages students to work and learn independently while facilitating, monitoring, and evaluating the students' practice.

Project-based learning moves away from the traditional teacher-centered model that is usually adopted in education.

Project-based learning is characterized by three principles, according to Schneider et al. (2002): (1) learning that involves students in real-world projects through which they develop and apply skills and knowledge; (2) learning that requires students to draw information from multiple resources in order to solve problems; and (3) learning in which curricular outcomes can be identified up-front but in which the outcomes of the student's learning processes are neither predetermined nor fully predictable. In the next paragraphs, we explore examples of project-based learning approaches.

Han et al. (2015) explored the application of project-based learning in science, technology, engineering, and mathematics (STEM) curricula. They studied how project-based activities affected high school students of different performance levels over a long period of time (3 years). The results of their study showed that low-performing students benefit more from PBL activities than medium and high performers. Low-performing students demonstrated significantly higher growth rates on mathematics scores than high- and middle-performing students over 3 years. In the same study, it was shown that a student's ethnicity and economic status were significant predictors of academic achievement. This implied that students from different backgrounds than the dominating one may have more opportunities to communicate with peers and teachers than they would in a traditional classroom and, thus, they benefit more from PBL activities with respect to performance. This finding has been confirmed by similar studies (Capraro et al. 2010).

Lee et al. (2015) studied collaboration as a twenty-first century skill that can be acquired as a PBL outcome. Furthermore, they attempted to identify how social skills relate to conflicts and how the lack of such skills affects collaboration on individuals and groups. Their findings suggested that task and process conflicts were often transformed into relationship conflicts when students lack social skills. However, when it came to reducing conflicts within groups and to promoting

collaboration, group-level social skills were more influential than individual social skills.

Avouris et al. (2010) reported and discussed their experience when using a mixed approach to teaching an introduction to programming and algorithms during a first-year university course. Their approach combined synchronous collaborative problem-solving along with asynchronous collaboration through project work.

Collaborative Game-Based Learning

Game-based learning (GBL) is an educational approach that capitalizes on *gameplay* in order to achieve predefined learning goals (Shaffer et al. 2005). Contrary to gamification – where gaming features, such as rewards and badges, are used to offer incentives and to motivate students – game-based learning involves the redesign of learning activities so that they will assimilate the fundamental characteristics of games: plots, artificial conflicts, and rules of play (Salen and Zimmerman 2004).

Research argues that educational games can scaffold students' motivation and improve their performance (Burguillo 2010; Papastergiou 2009). Furthermore, game-based learning can offer opportunities for constructive interactions with others that may lead to successful learning episodes. In this context, Voulgari and Komis (2010, 2011) explored the use of massively multiplayer online games (MMOGs) as environments for the emergence of collaborative learning. The authors studied how inherent elements of MMOGs can facilitate collaborative learning and how it is possible to apply collaborative learning principles to the design of MMOGs to promote effective interactions among players. Next, we provide some examples of collaborative game-based learning applications.

Sung and Hwang (2013) used a collaborative game-based learning environment to support students to organize and share knowledge during gameplay. They found that the collaborative gaming environment had a positive effect on students' learning motivation and achievement.

Chen et al. (2015) compared single-player GBL to collaborative GBL. Even though they found significant improvements in learning

outcomes that the authors attribute to GBL, no difference was found between the single-player and the collaborative condition. Nonetheless, the authors suggest that collaborative game-based learning allows students to reconstruct or co-construct knowledge and encourages collective problem-solving and discussion of rich descriptions of science concepts. Furthermore, they pointed out that positive group dynamics – where no conflicts between individuals exist – are necessary for an efficient student practice. Therefore, group formation is a key factor to success in collaborative game-based learning approaches.

Collaborative Learning Scripts

The goal of collaborative learning scripts (or collaboration scripts) is to structure and to scaffold interactions between peers in order to direct and coordinate collaborative practice (Dillenbourg and Jermann 2007). In other words, they script the students' activity to invoke meaningful interactions that lead to learning and avoid harmful interactions that may disrupt fruitful collaboration. Collaboration scripts capitalize on the notion of scaffolding, that is, the support learners receive in order to successfully carry out a task that they would not be able to accomplish without help. This support can refer to *content* (e.g., knowledge about a domain that is required by a learning activity but that a student does not have when starting the activity) or to the *structure* of collaboration (e.g., guidelines about communicating with peers or sharing information) or even to *both* content and structuring.

According to Kollar et al. (2006), collaboration scripts consist of at least five central conceptual components that can be used to formally define them. These components are (1) the *learning objectives* that are pursued with the use of scripts; (2) the *type of activities* that the scripts direct students to engage with; (3) *sequencing*, that is, the planning of activities or tasks that the student will carry out; (4) the *role distribution* among the peers that defines their responsibilities and contribution; and (5) the *type of representation* that will be used to communicate the collaboration script to students.

Dillenbourg and Hong (2008) distinguish between two categories with respect to the script's focus level, that is, the dimension or aspect of collaboration that the script aims to address:

1. *Micro-scripts*, which focus on the communication between peers. Typical examples are scripts used in argumentation learning that aim to teach peers how to facilitate argument construction (Weinberger et al. 2010).
2. *Macro-scripts*, which deal with the organization of the learning activity, such as the description of learning tasks, roles, and groups. Typical examples of macro-scripts are adaptations of Jigsaw, such as Concept Grid, or ArgueGraph (Dillenbourg and Jermann 2007).

The use of scripts has been studied extensively in argumentation and discourse. Stegmann et al. (2007) studied the use of scripts to facilitate argumentative knowledge construction. Their research suggested that scripts could have a positive impact on knowledge construction and knowledge acquisition, on argumentation, as well as on the formal quality of arguments. Weinberger et al. (2005) explored the use of computer-supported collaboration scripts to facilitate argumentative knowledge construction, either by supporting single argument construction or by supporting the construction of argumentation sequences. Their results showed that learners with scripts argued better and acquired more knowledge on argumentation than learners without scripts.

Näykki et al. (2017) studied the use of collaboration scripts from a socio-cognitive monitoring and socio-emotional monitoring perspective. In particular, the authors used collaboration scripts during a first-year course for teacher education students. The objective was to study how socio-cognitive and socio-emotional monitoring processes differentiated during more and less active script discussions. Their results showed that students used the script more in the beginning of the collaborative activity as a means of oneself's orientation to the group and the task.

Wang et al. (2017) explored the use of scripts that could adapt to students' self-regulation skills.

In particular, the authors tested whether the use of scripts that the students could adapt, based on their self-perceived needs, would have an impact on their self-regulation. The results of their work suggested that students who worked with adaptable scripts engaged in more metacognitive activities than those who worked with nonadaptable scripts. Also, the use of adaptable scripts was associated with more monitoring and reflection activities than the use of no scripts.

Collaborative scripts have been criticized for leading students to superficial interactions that do not indicate actual collaboration, when they are designed poorly. It has been argued that collaboration scripts can restrain and restrict collaboration episodes from developing naturally. Over-scripting may lead students to mimic the behavior that the script is anticipating from them – in a way, adopting a “gaming the system” behavior – without in reality engaging in the cognitive and social processes that are necessary for learning (Dillenbourg 2002).

Vogel et al. (2017) conducted a meta-analysis of scripting in order to look closer into the benefits and potential drawbacks of collaboration scripts. Their research showed that although the use of scripts leads to a small positive effect when it comes to domain-specific knowledge, scripts have a large positive effect with respect to collaboration skills.

Important Topics, Open Questions, and Future Directions

In this section, important topics for collaborative learning, open questions, and future research directions are discussed. In particular, the role of technology and the role of the teacher in collaborative learning are elaborated, and future directions and open challenges with respect to research and practice are discussed.

The Role of Technology in Collaborative Learning

The use of computer systems in education is an active research field due to the growth of popularity of computer systems and their use in everyday

life. Since the 1970s and up to this day (2019), intelligent tutoring systems (ITSs) aim to offer targeted and personalized tutoring by tailoring the needs of students and, thus, improving learning outcomes (Corbett et al. 1997). ITS-related research deals with designing activities that adapt to students' needs and prior knowledge. For ITSs, the student is considered an individual unit who learns while one practices with learning material. Because of the lack of social interaction, ITSs were criticized since education and learning are not only about providing knowledge and mastering skills but also about integrating students in a structured society of information and knowledge (Hawkins et al. 1982).

Collaborative learning addresses this criticism since it supports groups of students learning together while collaborating to achieve a common goal. In collaborative learning, technology is used to support collaboration between learners by providing means for communication and coordination, rather than providing sophisticated personalized instruction (Stahl et al. 2006). However, apart from a useful tool, technology in collaborative learning is also crucial for shaping research as well as learning and teaching practices. On the one hand, new learning paradigms such as mobile learning – that is, the educational approach where learning is mediated by using portable devices such as smartphones or tablet computers (Sharples et al. 2009) – have emerged from integrating new technologies in our common practice. On the other hand, teachers adapt the way they teach in order to accommodate changes introduced by technological advances (Jahnke and Kumar 2014).

A typical example for the impact of technology on shaping research in collaborative learning but, most importantly, on learners' practice is the paradigm of massive open online courses (MOOCs). Over the past few years, MOOCs have become very popular. Massachusetts Institute of Technology (MIT) and Harvard University, in a joint statement in January 2017, announced that in 4 years 2.4 million unique users participated in one or more MITx or HarvardX open online

courses, while, on average, 1554 new, unique participants enrolled per day (Source: <http://news.mit.edu/2017/mooc-study-offers-insights-into-online-learner-engagement-behavior-0112>).

It is evident that technology and its impact on learning should not be ignored or downplayed. On the contrary, technology can offer valuable tools that may contribute to improving teaching practices and learning gains when successfully integrated in educational approaches and designs.

The Role of the Teacher in Collaborative Learning

The teacher's role in collaborative learning classrooms is very different from the teacher's role in traditional classrooms (Cohen 1994). In the former case, the teacher, apart from instructing, is responsible for coordinating and supporting the collaborative groups. Furthermore, the kind of support the students need is different in collaborative scenarios from that in traditional classrooms. The students need to communicate effectively and collaborate successfully with their peers. Even though one of the premises of collaborative learning is that students learn by self-reflection and self-regulation which are triggered in collaborative learning settings, interventions by teachers remain necessary when students lack the required skills. Effective collaboration does not happen out of the blue; it requires careful planning of the learning activity and even training the students-peers by using examples of good collaborative practices (Voyiatzaki and Avouris 2014).

A common problem that teachers face in collaborative learning classrooms is to effectively monitor the practice of working groups and to provide support when necessary (Chounta and Avouris 2016; Van Leeuwen et al. 2015). Monitoring collaborative learning activities may refer to:

- Monitoring the *quality of collaboration*, that is, ensuring that the students collaborate in a meaningful and fruitful way without conflicts or miscommunication

- Monitoring the practice of students toward *the learning objective*, that is, ensuring that the learning goal will be achieved by identifying potential misconceptions to prevent failure

Thus, the teacher's goal is to support students when it comes to the collaborative practice but also to the learning objective (Voyiatzaki and Avouris 2014). Furthermore, in the case of collaborative learning activities in a classroom, the unit of analysis alternates between three levels: (1) the individual student, (2) the collaborating group, and (3) the classroom (Stahl et al. 2006; Webb et al. 2006). In order to successfully coordinate the learning activity, the teacher has to assess the students' performances and interactions with respect to these three levels (Voyiatzaki et al. 2008). The workload that teachers have when monitoring and orchestrating collaborative activities becomes even higher when students are not physically present but instead collaborate in virtual groups over the Internet. Therefore, there is a prominent need for tools to support teachers in course orchestration (Chan 2011).

Future Directions

The rapid technological advances have impact on education in general and on collaborative learning in particular. Over the past few years, research on collaborative learning has focused on how to open up *learning communities* and make them easily accessible for everyone (e.g., with MOOCs).

As the name suggests, MOOCs offer open and accessible learning for almost everyone. Every individual with access to a computer and the World Wide Web (WWW) can participate in a wide range of MOOCs depending on her/his interests and learning preferences. MOOCs have also had an impact on research in collaborative learning due to their social aspect. Learning in MOOCs can be supported through social interaction of individual learners with large communities. MOOCs use online discussion forums in order to facilitate communication, information exchange,

and knowledge building among the members of a community. Ongoing research in MOOCs focuses on identifying what kind of user interactions can be characterized as meaningful, thus promoting communication and, consequently, information exchange and knowledge building (Gillani et al. 2014).

Social network analysis and machine learning offer valuable analytical tools to identify the *roles* students adopt when they engage in social interactions, how these roles affect student participation in MOOC forums, and students' performance (Hecking et al. 2017; Wise and Cui 2018). Open questions lie in the way MOOC activities to create meaningful interactions between participants are created. Another challenge is how to provide personalized feedback to students and guide them to adopt knowledge-contributing and knowledge-building behaviors.

In addition to collaborative learning practices, there is a strong need for analysis and evaluation techniques for learning activities. Through analysis and evaluation, it is possible to inform research and practice about their outcomes and plan further improvements. The richness of data collected by applications that facilitate learning activities and the computational approaches that are available for analyzing these data offers a promising approach to improve our understanding of learning. The term *learning analytics* is typically used to refer to the process of data collection and analysis for understanding and assessing learning (Gašević et al. 2015). In collaborative learning, learning analytics are used to gain insights about the underlying learning mechanisms that are activated from social interaction, to assess the learning outcome, but also to provide valuable information about collaboration as well. Open questions are about the way computational models combine data from various sources in order to assess student performance, to predict the outcome of a learning activity, and to prevent student dropout or failure are used. Furthermore, ongoing research explores the potential connection between learning analytics and learning design, that is, how data-driven approaches can inform

course designers and support them in adapting and addressing their specific needs.

A promising trend in collaborative learning practices adapted in classroom settings stems from the *maker movement* and modern DIY (Do it Yourself) communities (Kuznetsov and Paulos 2010). They aim to exploit the benefits from adopting this culture in a formal educational setting. The key point of the maker culture is the creation of artifacts through a creative process in a social arena (Sharples et al. 2014). These artifacts are more than products of an assignment. In essence, they reflect the experience of the maker: what she/he learned, what she/he communicated, and what she/he shared.

The maker movement came together as a “product” of a technologically influenced DIY community (Cavalcanti 2013). Projects in this context are typically technology-driven and combine several disciplines such as crafting and electrical engineering. While DIY projects do not necessarily require group activities, one of the core aspects of the maker philosophy is a maker space. This refers to a real, physical space, which serves as a persistent location for idea and knowledge exchange, planning, communication, and implementation. Modern maker spaces build on the idea of people getting together to exchange their knowledge and their tools. This concept also inhibits social aspects: participants usually share a common space, in some cases they share accommodation, and they participate in social events. Latest trends demonstrate the usefulness of institutions such as coding camps, with some companies establishing such camps as a means for vocational training (Lewin 2014).

Promising new topics for research and practice emerge from the integration of technology in education. The traditional classroom is undergoing change and adaptation in order to accommodate new paradigms that employ technology to scaffold learning. However, technology is not seen as a tool to promote learning on an individual level but rather as a means to support the members of a classroom (i.e., the students as well as the teachers) to establish a “networked society.” In such a society, students work together on artifacts using technology to coordinate and monitor their

activities (thus, scaffolding reflection and self-regulation), and teachers orchestrate learning activities enabling social arrangements and interactions to achieve the desirable learning outcomes.

Comparative Analysis of E-Governance and IT Governance

Monica Nehemia, Irja Shaanika and Tiko Iyamu
Department of Information Technology, Cape Peninsula University of Technology, Cape Town, South Africa

Introduction

This entry presents a comparative analysis of the e-governance and information technology (IT) governance. The aim is to gain better understanding of the differences and similarities between the two concepts and propose their complementary use.

Many organizations set up computing environments with the main aim of providing improved, effective, and efficient services to their clients, including better collaboration with its partners (Lunardi et al. 2016). This is owing to the popular

believe that IT enables organizations for competitive advantages (Fernando et al. 2016). In some government organizations, the activities of the computing environments are often invoked through e-governance initiatives, with the purpose of providing digitized services to the public at large. E-governance is the process through which many governments make use of IT, to provide services to her citizens (Liu and Liao 2011). The concept of e-governance is also employed by some public organizations, in carrying out activities such as enforcement of public policies, decision-making, and knowledge management (Kumari and Singh 2016).

However, computing environments are not free or immune of challenges, such as risk mitigation, security, reliability, and interoperability management (Dawe 2008). These challenges hinder organizations from operating affectively and achieving their set goals and objectives. Due to various challenges and risks, it was reported that “it is very difficult for the government to keep up with the developments of information and communication technology (ICT) implementations spontaneously” (Kumari and Singh 2016). Some of these challenges ignite many organizations including government’s administrations and agencies to adopt various governance approaches, such as IT governance, in order to improve systems performance, guide technology deployment, manage ICT process, and measure deliverables within their computing environments. Also, some of the challenges could spin from an understanding of the approach, which manifests from the definitions (Lunardi et al. 2016).

The definition and description of the governance approach can be very broad, which bring about vagueness that makes specific goals to be difficult to achieve. For examples, governance is defined as “processes and institutions, both formal and informal, which guide and restrain the collective activities of a group” (Keohane 2002), and Bevir (2012) attempts to clarify the concept by stating that governance include “all processes of governing, whether undertaken by a government, market or network, whether over a family, tribe, formal or informal organisation or territory.” To avoid such circumstance, governance’s definition

is narrowed to the context of this study, which is about rules, processes, and control of an institution or legal entity.

Irrespective of the angle and premise that an individual or organization including government views governance, it is of vital importance to processes and activities within an environment. Thus, many organizations adopt the concept of governance, such as e-governance and IT governance (Ali and Green 2012). However, the deployment of these concepts is a challenge to many organizations including government organizations (Gupta and Bansal 2013). The challenges could be a manifestation of a lack of understanding about the two terms within organization’s computing environments. E-governance and IT governance are broad and ambiguous, which in turn implicates difficulty and inaccurate assessment of IT activities (Cho et al. 2010). Chunyang stated that IT governance is a new challenge that organizations are faced with Chunyang (2010).

The concepts of e-governance and IT governance are concurrently or complementarily employed in computing environments such as the public sector. In common, they share the word governance. The focus of governance is more about whether IT efforts are enabling and supporting organizational strategic goals (Cervone 2017). Other than that, the concepts differ in many ways, such as e-governance entails project and IT governance entails policies (Saxena 2005). Many people from both IT and business (government included) continue to interchangeably or loosely use and sometimes attempt to wrongly apply the concepts in their environments. Primarily, this is attributed to the fact that some employees do not have clear or full understanding of the concepts. Some earlier definitions of the concepts did not help matters either, as they add to the confusion of the misunderstanding or loosely use of the concepts, by being so broad.

Comparative Between E-Governance and IT Governance

The primary aim of the comparative analysis was to provide distinction between the e-governance

and IT governance. The analysis was comparatively carried out from two viewpoints, component and use. The two viewpoints enabled the interrogation of e-governance and IT governance applications, which is critical in defining the comparative of the two terms, respectively.

Component

The component constitute element such as scope, focus, and depth. These elements were selected primarily because they define the concepts and form the basis of organizational requirements and specification for deployment. Therefore, through these elements, differentiation can be made clearer and understood better.

- i. Scope – The scope of the e-governance is primarily on the digitalization of government's processes and activities (Chun et al. 2010). This includes its socioeconomic and geopolitical commitments and orientations (Saxena 2005). IT governance tries to address questions such as what IT capabilities we need to digitize business processes and how will we go about it (Cho et al. 2010). The scope of concepts of e-governance and IT governance are clearly different in scope (Carter and Bélanger 2005). Therefore, they should not be misunderstood for one another.
- ii. Focus – The focuses of the e-governance is on government administration and its activities. IT governance ensures that e-governance is attainable through the development, implementations, and applications of IT standards, policies, and strategies in an effort to deliver IT/business alignment (Al Athmay 2015). Therefore, IT governance focuses on the development of strategies that are needed to monitor and ensure that the right resources technical as well as nontechnical are applied in the selection, development, implementations, utilization, and maintenance of ICT artifacts (Karentzeni and Gouscos 2013).
- iii. Depth – Based on scope and focus, the IT governance is considered to be broader than the e-governance. This consideration is also mainly because the e-governance is a concept that is applied only within government

organizations (Cordella and Bonina 2012; Yudatama et al. 2017), while the IT governance can be applied in a wider spread, from private to government organization, including nongovernment organizations (Shibu and Naik 2017). Also, in scope and depth, the IT governance concept is constantly reviewed to ensure alignment between business and ICT's goals (Cho et al. 2010). Thus, IT governance drives the ICT capabilities that are needed to ensure that an organization become competitive through the ICT resources.

The Use of the Concepts

The actual use of the e-governance and IT governance is one of the main differentiate factors between the concepts. E-governance is used in the public sector, referred to as an ICT innovation management process (Verma et al. 2017), while IT governance is concerned with IT decision-makings, structured processes, policies, responsibilities, and monitoring of ICT in an organization (Serrano et al. 2017). Thus, an understanding of the concepts helps to avoid the confusions that are associated with them, therefore improving the efficiency of their deployment. This includes loosely and interchangeable use of the concepts, which sometimes affects their deployment and objectives. The table below presents the comparison, which is intended to guide their use in the Namibia government, and can be similar to other environments. The comparative analysis was interrogative, by using questioning elements of prefix, which include what, who, how, when, where, and why.

Table 1 is briefly explained to gain better understanding:

- i. What: defines the two terms, e-governance and IT governance, in context to the Namibian public sector.
- ii. Who: defines the initiators and accountable individuals/office, which are not necessarily the implementers of the projects. However, they influence the process in that they are accountable for the success or failure of the projects.
- iii. How: refers to the processes that are undertaken in order to realize the goals of the

Comparative Analysis of E-Governance and IT Governance, Table 1 E-governance and IT governance comparative analysis

	What	Who	How	When	Where	Why
	<i>Material (what it is)</i>	<i>People</i>	<i>Process</i>	<i>Time</i>	<i>Location</i>	<i>Motivation</i>
E-governance	(i) The implementation of ICT to deliver government services to citizens and other stakeholders (ii) To enable and support political processes and activities	Heads of government/ political leaders (ministers)	Defined economic, social, and political objectives translated into ICT specifications and projects	Long-term projects with tangible outcomes achieved within a set time frame. Thereafter it is subjected to maintenance and upgrade	Deployed across all ministry's and governmental agencies	Availability of 24/7 online government services and information to citizen and all stakeholders in order to deliver effective efficient services
IT governance	Structured oriented for controls and risks management of defined ICT projects	Accounting officers of ministries (permanent secretaries) and government agencies (CEO)	By defining policies, principles that are used to manage IT/business alignment through project implementation	A standing IT/business policy established, whereby all ICT projects are subjected to		Ensuring effective and efficient management of IT/business projects services delivery

e-governance and IT governance within an organization.

- iv. When: refers to the time frame within which the e-governance and IT governance initiatives exist and are deployed within an environment.
- v. Where: it refers to the level at which the e-governance and IT governance are deployed within the government environment.
- vi. Why: explains the objectives of developing and implementing e-governance and IT governance initiatives in an organization.

Findings and Discussion

This discussion is based on the comparative analysis carried out above. This discussion is divided into two main sections, commonality and distinction, between the concepts of e-governance and IT governance.

The Commonality

Even though the objective of the entry was not to focus on what is common among the concepts, it helps to gain an understanding of the relationship, as well as the differentiation between the concepts. Also, the commonalities help to gain better perspective on why the concepts are loosely and interchangeably used in many environments.

Both e-governance and IT governance are ICT-related approaches. This means that they are employed for the same objectives, which are to enable, support, and manage processes and activities from the ICT perspectives. The overall objective of governance is to ensure that the ICT projects and environments are aligned to the strategic objectives of an organization (Cho et al. 2010). However, the concepts are deployed differently and at different sizes or scope.

The e-governance and IT governance can be used at either operational or strategic or both levels within an organization. As shown in

Comparative Analysis of E-Governance and IT Governance, Fig. 1 E-governance and IT governance implementation

Fig. 1, both concepts need to be implemented. Project implementation is the medium through which both e-governance and IT governance are realized. Thus, ICT projects can be implemented, using the same resources.

E-Governance

Primarily, the e-governance is deployed with a vision that is divided into three main areas: (i) to avail ease of access of information to the citizens; (ii) to monitor and evaluate public services that are delivered to the citizens; (iii) and to support and enable collaboration between government (including its agencies) and its stakeholders and partners. E-governance thus focuses on socioeconomic activities and political agenda of the government (Potnis 2010). As a result, government agents (ministers and other senior personnel) rely on the e-governance to execute many of their tasks and responsibilities, often through ICT projects.

ICT Projects

Organizational vision is decomposed into goals and objectives that need to be fulfilled through the execution of the e-governance and IT governance, for various activities. The execution is carried out through ICT projects as shown in Fig. 1. IT governance is implemented in public organizations to better serve the implementation of ICT plans, projects, and programs. These ICT plans, projects, and programs can be an e-governance. The ICT projects are derived from the individual mandate and operations of each ministry, which are aimed to automate services. The ICT projects are

defined, developed, and implemented at the ministerial level, in conjunction with the other agencies. On one hand, IT governance guides IT projects. On another hand, IT governance is implemented through IT projects.

IT Governance

The IT governance is used to guide the selection, development, implementation, and application of ICT infrastructures and supporting resources in an organization. However, there are challenges that are associated with the tasks, at all levels, which have become critical due to its misalignment and failures. This can be attributed to weak defined priorities and lack of support from the executives of an organization.

Also, the IT governance is used to ensure that management from both IT and business units do support and implement ICT projects that are aligned to the organization's objectives (Cho et al. 2010). The government personnel of the government administrations often heads the committees that are responsible and accountable for the implementation of IT governance in the organization, in accordance to set standards, policies, and processes. The personnel ensure that all ICT projects are subjected to the IT governance standards.

Implementation

The operationalization of the e-governance and IT governance is done through the implementations of various ICT projects. The implementation consists of technical and nontechnical factors, which include humans (Orozco et al. 2015). These factors require governance in order to avoid or minimize complexities and risks and promote productivity. Under the auspices of the leadership (executive) of a government representative, each ministry develops and implements its own ICT projects. This is intended to guide and ensure that ICT projects undergo due diligence and resource allocation are well managed. The implementation process is conducted through a project plan consisting of a matrix project team, as well as the organization's executive personnel, for accountability. In the National Computing Centre's document of 2005, the implementation of the

IT governance was defined as a project and not as a once-off. The document further describes IT governance as the first key to success.

The commonality between the e-governance and IT governance also manifests from the implementation of ICT projects in an organization. There are two main differences, which include (1) e-governance is more concerned with digitization of business processes through ICT projects and (2) IT governance focuses more on processes, policies, standards, and control measures that are set to guide the selection, deployment, and support of all ICT projects in an organization.

The Distinction

It is imperative that a distinction is drawn between the concepts of e-governance and IT governance. The distinction helps to curb the confusion and the loosely, interchangeably use of the two concepts. From the analysis that was carried out in this study, the distinction is drawn along the lines of the following four factors: categorization, actual use, control, and dependency, as illustrated in Fig. 2.

- i. Categorization: e-governance is regarded as the automation or interoperability of systems, while the IT governance is considered a tool or approach that can be used to guide IT efforts across an organization and ensure that strategic goals are achieved (Cho et al. 2010). E-governance's objectives include the digitization of government processes, timely

processing, and sharing of information to citizens and other stakeholders (Shaanika and Iyamu 2015). However to be able to objectively implement the e-governance system, tools and approaches are employed. This is to guide and ensure that the appropriate ICT capabilities in terms of infrastructures, processes, and management skills are selected for successful e-governance operations in an organization.

- ii. Control and dependency: the implementation, use, and maintenance of the e-governance require guidance and support, which can be provided by the IT governance. The absence of effective IT governance causes poor performance of ICT resources, runaway IT projects (e-governance), and possible demise of the IT department in an organization (Ali and Green 2012). Within the government organizations, the selection, development, and implementation of ICT artifacts are carried out in accordance to the definition of the IT governance in an environment. Without IT governance, it is always difficult or near impossible to realize e-governance's objectives. Therefore, in government organizations, it is common to find both e-governance and IT governance in operations.
- iii. Actual use: the e-governance is a system that is specific to government environment, used to deliver services. The application of ICT to improve government services is known as e-governance (Prabhu 2013). Schnoll

Comparative Analysis of E-Governance and IT Governance, Fig. 2

E-governance and IT governance distinction

explains that e-governance encompass local, regional, and central governments and their agencies, as well as other public organizations such as schools and healthcare institutions (Schnoll 2015). Thus e-governance is a concept that can only be applied within the government environments.

However, the IT governance is an approach that can be applied to the entire computing environment of any organization. This implies that IT governance can be applied at both private and public organizations' environments. IT governance such as COBIT ensures that ICT resources are managed by ICT processes to achieve the ICT objectives that meet an organization's business requirements (Rubino and Vitolla 2014).

Conclusion

The similarities observed between e-governance and IT governance are that both ensure the alignment of IT/business objectives, and they are deployed through ICT projects. Specifically, the e-governance focuses on the use of ICT to render online services to its citizens and stakeholders, while IT governance is concerned with the ICT standards and policies to guide the selection, development, and implementation of ICT infrastructure and resources. Both approaches can be implemented in the organization as each has its own distinctive objectives. This distinction is important for politicians and senior government personnel. This is to ensure that they understand their investment on and use of e-governance as a system and IT governance as an approach. That helps with decision-making about the concepts within an environment.

This entry can be useful to academics in educating aspiring specialists in the field of computing, in that it can help to gain better understanding of the differences between the concepts. In addition, the entry can be of vital importance to other interested persons and groups, such as employment agents. The distinction between e-governance and IT

governance as presented in the entry can add valuable input in their classification and categorization of job roles and responsibilities.

Competency Models in Computing Education

[Assessment](#); [Learning outcome](#)

Towards the Term Competency

The terms competence and competency have been topics in academic discourse in the educational and vocational context as well as in psychology for several years. Due to their origin, the terms often denote the same construct. Le Deist and Winterton (2005) have explained the different usages of the terms throughout history as well as in different scientific areas. They repeatedly point out the inconsistent usage of both terms but were able to make out different meanings with a partly overlapping understanding. Thus, they come up with three different inspections on both terms, a functional, a behavioral, and a holistic approach. The meaning of the terms covers huge quantities of individual features and traits, such as job-related skills, knowledge, abilities, know-how, performance, etc. A more specific definition was given by Weinert in his works for the OECD, where he defined competences as “the readily available or learnable cognitive abilities and skills which are needed for solving problems as well as the associated motivational, volitional and social capabilities and skills which are in turn necessary for successful and responsible problem solving in variable situations” (Weinert 2001). Klieme et al. (2008) refer to Weinert's definition but exclude the meta-cognitive aspects due to assessment efficiency. They define competencies as “context-specific cognitive dispositions that are acquired by

learning and needed to successfully cope with certain situations or tasks in specific domains.” The important part in all of these definitions is that competencies relate to specific contexts and can be acquired and developed by means of a learning process, although it is not possible to teach competencies per se. They are always the result of an interaction process with the subject someone aims to be competent in.

For further descriptions the term competency will be used. In general, the term denotes a latent construct, which means it is not directly visible but is responsible for certain visible actions. The quality of the interaction of a person with a task is then the assumed degree of competency this person has regarding the subject. For example, a person can be competent with databases. This could encompass being able to normalize a database, to query data from it, or to handle different representational forms such as ER models. The concept of competency must not be confused with the concept of intelligence. Both are assumed underlying psychological traits of persons, yet competencies can be altered by learning and training processes and are context-dependent, while intelligence refers to an extensive construct which is much more difficult to influence via learning processes. The competency of a person becomes manifest when the person is confronted with a problem, where the competency is needed to master the situation. The respective level of competency enables the person to deal with the problem in a more or less adequate manner.

The educational goal is then to focus learning on the development of competencies instead of inert and compartmentalized knowledge of facts. The underlying assumption is that the developed competencies won’t only account for success in school but enable individuals to succeed in later parts in life, such as in vocational or higher education.

All mentioned points have been summarized in great detail in (Klieme et al. 2008) and have been clarified for computer science education in (Hubwieser and Sentance 2018).

Modeling Competency: Competency Models

If learning outcomes in educational processes are targeted toward the development of competencies, it is necessary to clarify which skills and abilities define said competencies and how this should be assessed in order to investigate whether educational interventions were successful. It is thus obvious that in terms of assessment, competencies have to be defined in a pragmatic way. This enables educators to uncover existing problems and to offer individualized support. The gathering of competencies regarding their different areas of performance is usually defined in competency structure models like in the former example of competencies regarding databases. In competency level models, the situational demands to perform a certain task on different ability levels are given to provide possibilities of interpretation of certain task performances. Both are different aspects of the same construct, and as such they complement each other. A third kind of model are competency development models. As the name might suggest, these models deal with the development of an individual competency over time, such as the development of programming competency during the learning process.

General Approaches when Modeling Competencies

An important first step during the process of modeling competencies is the definition of skills and abilities that are necessary to perform tasks in a competent manner. For example, “being competent in the area of object-oriented programming” includes the knowledge about object-oriented concepts, the skills to deal with a formal language like a programming language, as well as the abilities to devise a generalized plan (algorithm) including to review and adapt that plan in case of failure. Of course, each of these areas (often referred to as competency dimensions)

can then still be divided in further subareas (sub-dimensions). A similar approach can be done for every other field where people can be considered competent. Furthermore, on the search for specific competencies, it is not only worth researching the literature for skills and abilities that are needed to solve a certain problem but also for those activities that are often troublesome for a significant proportion of students. Mastering such a troublesome task (such as understanding the concept of polymorphous method calls) can be considered as a gain in competency in this specific area or to the whole competency, which in turn already hints toward specific characteristics of competency levels.

Transforming Competency Models into Psychometric Measurement Models

In order to actually assess theoretically defined competencies, it is necessary to choose an appropriate psychometric measurement model. In the assessment process, test persons are usually confronted with situations that require a certain degree of competency, e.g., a classical pen and paper test situation. The measurement model helps to interpret the results of assessed persons and connects the manifest behavior, usually the test results, with the underlying latent trait, such as the assumed competency. It is important to decide based on theoretical decisions which measurement models should be considered beforehand. If, for example, the assessed construct is assumed to be a latent construct which is distributed on a single continuum, the probabilistic models of item response theory (IRT) are currently state of the art, e.g., the Rasch model. If the test situation assesses skills and abilities from several proposed competency dimensions, researchers can make the choice for multidimensional IRT models (Hartig 2008). Referring back to the example of object-oriented programming competencies, it seems obvious that every constructive programming task usually involves several of the proposed competency dimensions. To program successfully means to handle a formal language, to devise an algorithm, and to

implement it with the help of object-oriented design concepts at the same time. If the probability to solve an item of a test correctly depends on abilities from several dimensions of the proposed competency model, the result can be evaluated under so-called within-item multidimensionality. This would be the case for a typical task like “adding a method to a given class in an object-oriented program.” If all items in a test can be matched to exactly one dimension of the multidimensional competency model (not necessarily the same for all items) and the test results are modeled under the assumption of multidimensional abilities, then this is called between-item multidimensionality. An example would be items which assess the knowledge about object-oriented concepts separated from the knowledge about the syntax of a given programming language. In general, models of within-item multidimensionality have the potential to represent more realistic phenomena, while at the same time they’re more difficult to evaluate.

The choice for models of IRT is also justified by the fact that two aspects are taken into account at the same time: the difficulty of an item and the ability of a person. As a result, they can be mapped onto the same scale, which makes them comparable. With regard to a latent construct, it is possible to order items regarding their difficulty (from “easy” to “hard”) and to order persons regarding their competence (from “unable” to “able”). This requires a different point of view, since comparing the ability of a person with the difficulty of an item is only possible with means of a probabilistic function and has been described in great detail in (Hartig 2008).

Existing Competency Models in Computing Education

A recent example in modeling competencies in the area of informatics modeling and system comprehension was done in the project MoKoM (see Linck et al. 2013). Referring to the former process of the OECD for defining and selecting key competencies, educational documents such as curricula and educational recommendations were

analyzed concerning skills and abilities related to informatics modeling and system comprehension. This resulted in the definition of five different dimensions, system application, system comprehension, system development, dealing with system complexity, and non-cognitive skills, where the latter didn't play any role in the assessment process. Competency in the area of informatics modeling and system comprehension is then always a combination of these assumed independent categories and is determined by how good an individual performs in the single dimensions. The final status of the model is the result of a verification process, where 30 experts in the field of computer science, computer science education, as well as computer science teachers reviewed it. In (Neugebauer et al. 2014) the authors describe the actual measurement process regarding the 4 cognitive dimensions using 292 items on 583 test persons. Evaluating the responses with means of multidimensional item response theory, the results delivered actual evidence that the assumed four dimensions have to be regarded as different ability dimensions. And this in turn has implications for teaching and learning processes as well as for assessment situations.

Kramer et al. (2016) described the derivation process for a competency structure model for object-oriented programming. In analyzing empirically verified competency models from different educational fields like mathematics, science, and music education, a common structure was derived and applied toward the existing scientific knowledge on the topic of OOP. They demonstrated the process of item derivation and could present first results of a test regarding the identification of object-oriented elements in source codes.

Introduction

At the turn of this century, educators and social scientists began to notice that youth who grew up having intensive, long-term experiences with technology – sometimes called “digital natives”

or “power users of technology” – appeared to think and solve problems differently from those with more limited technology experience. At the same time, computer scientists began to discuss how individuals living, learning, and working in an increasingly technology-driven world would become “advantaged” if they adopted the “ways of thinking” used by computer scientists. They began to describe the ways of thinking that would allow people to take advantage of the affordances of technology for the creative process, for solving previously intractable problems, and for producing new products and services. These trends converge in the concept we now know as “computational thinking.”

Over the past decade, computational thinking has become a global initiative for educational change. Countries around the world are now requiring computational thinking in compulsory education, considering it a needed skill to participate fully in our digital world, in particular, the rapidly changing, highly technical world of work (Bocconi et al. 2016).

This paper shares current definitions of computational thinking and the models/approaches to computational thinking found in today’s schools, discusses the challenges and issues related to computational thinking and its integration into already crowded curricula, and summarizes what we have learned about computational thinking through various strands of current research, illustrated with examples from the field.

Defining Computational Thinking

More than a decade ago, Computational thinking (CT) was proposed as a new “core skill” for all by Jeanette Wing, noted computer scientist and educator. Since then, the definition of CT in K–12 has evolved through a decentralized system, with independent groups working on CT issues pushing forward simultaneously. One of the greatest challenges in the field is the lack of consensus on a precise definition of computational thinking.

Computational Thinking as a Deconstructed Skill Set

Collective efforts to develop a definition of computational thinking include, among others, workshops in 2010 and 2011 sponsored by the US National Academy of Sciences, the “Shut Down or Restart” initiative undertaken by the Royal Society in 2012, and workshops organized by the Computer Science Teachers Association (CSTA) and the International Society for Technology in Education (ISTE).

The National Research Council differentiated computational thinking from computer literacy, computer programming, and computer applications (i.e., games and simulations). It broadened the term to include core concepts from the discipline of computer science (CS), such as abstraction, decomposition, pattern generalizations, visualization, problem solving, and algorithmic thinking.

The Royal Society (2012) offered a concise definition of computational thinking as “the process of recognizing aspects of computation in the world that surrounds us, and applying tools and techniques from computer science to understand and reason about both natural and artificial systems and processes” (p. 29).

CSTA and ISTE, in collaboration with leaders from higher education, industry, and K–2 education, developed an operational definition of computational thinking as a problem-solving process that includes, but is not limited to, the following elements: (a) formulating problems in a way that enables us to use a computer and other tools to help solve them; (b) logically organizing and analyzing data; (c) representing data through abstractions, such as models and simulations; (d) automating solutions through algorithmic thinking (i.e., a series of ordered steps); (e) identifying, analyzing, and implementing possible solutions with the goal of achieving the most efficient and effective combination of steps and resources; and (f) generalizing and transferring this problem-solving process to a wide variety of problems.

After a systematic examination of what is currently known in the literature, researchers,

particularly those with a CS background, define computational thinking as a thought process that utilizes elements such as abstraction, generalization, decomposition, algorithmic thinking, and debugging. Abstraction is the skill of removing characteristics or attributes from an object or an entity in order to reduce it to a set of fundamental characteristics. While abstraction reduces complexity by hiding irrelevant detail, generalization reduces complexity by replacing multiple entities which perform similar functions with a single construct. For example, programming languages provide generalization through procedures and parameterization. Abstraction and generalization are often used together, as abstractions are generalized through parameterization to provide greater utility. Decomposition is the skill of breaking complex problems into simpler parts. Algorithmic thinking is a problem-solving skill related to devising a step-by-step solution to a problem and differs from coding (i.e., the technical skills required to be able to write code in a programming language). Additionally, the algorithmic notions of sequencing (i.e., developing a series of instructions in an order necessary to perform a task) and flow of control (i.e., using looping, conditionals, and branching to dictate the order in which individual instructions or steps in an algorithm are executed) are also considered important elements of computational thinking. Debugging includes the skill to recognize when actions do not correspond to instructions and the skill to fix errors.

Computational Thinking (in Action) as Practice

As one strand of research focused on defining CT by disaggregating its elements, another emerged that explored the integration of CT into disciplinary learning through its practices. Lee et al. (2011) first suggested that CT skills are developed through practice in three phases as students are using, modifying, and creating technologies. As the use of the term CT gathered momentum, it began to emerge within the disciplines as well, most notably among the eight practice standards within the Next Generation Science Standards.

Weintrop et al. (2016) suggest four types of CT practices: data practices, modeling and simulation practices, computational problem-solving practices, and systems thinking practices. Some US states (including Massachusetts and New Jersey) see computational thinking as the thread running through and connecting digital literacy and computer science standards. The Massachusetts Digital Literacy/Computer Science Standards K–12, for example, includes Abstraction, Algorithms, Data, Programming and Development, and Modeling and Simulation in its Computational Thinking strand.

Working Definition

While there are clearly similarities between these two approaches, the differences are numerous. And as these initiatives operate independently, they run the risk of introducing to the field several disparate (and potentially conflicting) definitions of CT. As a result, although a decade has passed since CT was proposed, there does not yet exist a single precise definition of the concept. Voogt et al. (2015) argue:

For the purpose of conceptualizing CT and integrating it in education, we should not try to give an ultimate definition of CT, but rather try to find similarities and relationships in the discussions about CT. Finding these similarities and relationships will lead to a more concise description of “what matters” in CT and how to integrate it within K–12. (¶ 28)

Today most generally agree that computational thinking means formulating problems and their solutions in a way that a computer can be used as a processor to understand the problem or carry out the solution (Cuny et al. n.d.).

Approaches to Computational Thinking Education

Defining CT as disaggregated elements and defining CT as practices integrated into disciplines yielded two different approaches to CT education: (a) programming-centric approaches to CT education and (b) integration of CT within academic disciplines.

Traditional Programming-Centric Approaches

Unplugged activities. CS Unplugged, originally developed by Tim Bell at University of Canterbury (New Zealand), is a hands-on approach that teaches computational thinking and programming concepts through engaging games and puzzles that use cards, string, crayons, and lots of physical movement. Students learn about binary numbers and algorithms without using computer programming. CS Unplugged gained international attention when first introduced at ACM's Special Interest Group on Computer Science Education in 2007. Since then it has become used worldwide as a way to help youth experience computer science without having to learn programming first. Similarly, the Thinkersmith curriculum introduced a stand-alone set of unplugged activities for K-8 specifically designed to provide students with strong computer science foundations without using computers. Lessons in this curriculum, such as Binary Baubles, use materials found in games and crafts to teach authentic computer science concepts.

Building-block programming approach. The building-block programming approach deploys Logo or Logo-like programming languages, such as Scratch, to teach young students various computational thinking skills, such as abstraction, generalization, and algorithmic thinking. In these building-block programming environments, one creates computer programs by simply snapping graphical blocks together into stacks which represent sequences of instructions. In addition, these environments are usually "low floor" (easy to learn how to use) and "high ceiling" (affording the development of complex and sophisticated programs), allowing children to engage in rich programming activities with them.

Tangible programming. Tangible programming makes programming more direct and less abstract for young children by combining computer programming and tangible interaction using physical objects to interact with the computer. Tangible programming tools include: T-Maze, Tern, Toque, and Twinkle.

Digital game design and creation. A fourth approach for teaching computational thinking is digital game design and creation. According to this approach, learners can easily create objects

with visual representations and assign properties to them. Similarly, cMinds Learning Suite is a learning intervention that uses game-based visual programming toward building computational thinking skills. In studies that adopted cMinds Learning Suite in different European countries, learners who used this tool showed high motivation in engaging in computational thinking activities and improved problem-solving skills. Computational thinking tools such as agent cubes, spreadsheets, Mindmap, Boxer, and Logo have been shown to minimize the need for end users to write lines and lines of code and to simplify the ways students across disciplines are able to engage in computational thinking and further develop these skills.

Robotics. Educational robotics constitutes an attractive approach for developing computational thinking, because learners can directly interact with a robot and observe the immediate effects of their interactions on the robot's behavior (Angeli et al. 2016). Engagement with robotics through building and programming tangible and/or robotic devices is used by educators to engage learners in active, playful learning activities. Additionally, many studies indicate that engagement with robotics creates a high degree of student interest and engagement in STEM careers; positively influences school achievement; and science degree attainment.

Computer modeling and simulation. Modifying and creating computer models and using models as experimental platforms to run simulation experiments is an approach that has been used to engage students in computational thinking in middle and high school. In this approach, students use abstraction to recreate features of the real-world system that they deem important, implement the behavior of components of the system as algorithms, and analyze the data generated from running simulations to engage in argumentation from evidence. Results from a research study showed that after modeling and simulating a phenomenon, students were able to propose using computer simulation and describe the potential use of abstraction, automation, and analysis in a hypothetical study of a novel community issue (Lee 2011).

Disciplinary Approaches

As CT integration efforts increased, so did interest in what CT looks like in service of the disciplines. Building on greater recognition of the role CT plays in disciplinary learning, the National Science Foundation (USA) funded a program called STEM +Computing to address “the urgent need to prepare students from the early grades through high school in the essential skills, competencies, and dispositions needed to succeed in a computationally-dependent world through a strong foundation in computing and computational thinking through the integration of CT in STEM teaching and learning” (National Science Foundation 2017).

To guide teaching and learning of CT within the disciplines, NSF sought a new kind of computational thinking framework, one which captured and clarified what students were able to do using CT – and less able to do without it. Working with examples from more than 50 CT researchers and practitioners, Malyn-Smith et al. (2018) proposed five core “elements” that mirror powerful practices in CT-integrated fields (e.g., computational biology, computational chemistry, chemo- and bioinformatics, and computational astrophysics). These elements describe what CT looks like when integrated within disciplines and include the following: (a) understanding (complex) systems, (b) innovating with computational representations, (c) designing solutions that leverage computational power/resources, (d) engaging in collective sense making around data, and (e) understanding potential consequences of actions. This work provides a strong rationale for teaching students computational sciences to prepare them for participatory citizenship in a digital world and for success in tomorrow’s workplace.

Assessing Computational Thinking

While it is generally recognized that little research and development has been done to assess students’ CT capacities, the field is moving forward. In a brief overview of current literature on CT assessments, Grover 2017 described a range of approaches used to assess student learning. While progress in developing assessments for

specific computer science courses that teach computational thinking (e.g., CS Principles, Exploring Computer Science), researchers have found that assessing CT through programming has been challenging. Analyzing students’ artifacts is time-consuming and subjective, driving the development of tools such as Dr. Scratch. However, Grover also notes that it soon became clear that the existence of computational constructs in students’ code did not always translate into students’ CT competence. Rubrics developed to assess algorithmic thinking, abstraction, and code was found to be cumbersome. Innovators turned to gaming environments to assess CT and simulations to assess CT within a disciplinary context (e.g., science). Multiple-choice tests, providing opportunities for large scale assessments, were developed and are being used to assess students’ understanding of programming and computing concepts in countries requiring compulsory CT education. Artifact-based and scenario-based interviews of students were able to detect near transfer of computational thinking to solving new community problems, but this method is too time-intensive to be carried out in large scale.

While most efforts have focused on assessing the disaggregated CT elements identified in the discussion of defining CT above, new questions arise when considering CT from a disciplinary perspective. Do we assess the disaggregated elements of CT (e.g., abstraction, algorithms, and programming)? Or, do we assess students’ application of computational thinking within a context or discipline as they demonstrate understanding of complex systems, innovate with computational representations, or engage in collective sense making around data?

Current Challenges/Issues

Teaching and learning CT and integrating it across the curriculum face challenges at both the systems and implementation levels. Systemic challenges include developing a consolidated understanding of computational thinking, comprehensive integration of CT across the curriculum, systemic rollout, and policy support (Bocconi et al. 2016, p. 7).

At the implementation level, CT becomes a low priority when it is not required as part of compulsory education. Limited access to technologies (Internet capacities, funds for technology/robotics, technology consumables purchases, and maintenance) limits students' exposure to CT skill-building opportunities. Few jurisdictions offer computer science teacher licenses/ endorsements, which in turn limits the number of highly qualified CS teachers available to teach CT skills and integrate CT effectively across the curriculum. Teachers new to computer science and computational thinking require costly comprehensive programs of professional development over an extended period of time to become fully competent and comfortable with their role in teaching CT and integrating it across their curricula. Furthermore, with limited time in the school day, whether or not CT is included as a requirement for compulsory education, tensions arise when teachers are asked to integrate CT into an already crowded curriculum.

Teaching/learning issues include ongoing questions around when and how (and how early) to teach concepts such as abstraction and the basics of computer programming. Is CT best taught through programming or through the disciplines? How should teachers scaffold CT and CS skills/knowledge, integrate computational sciences, and use computational tools to build bridges between school and future work when tools, techniques, and practices are changing with rapid technological advances? What needs to be included in the teaching and learning of CT (and CS) in light of the rapid rise of the machine age? And, of course, what should we assess in CT (disaggregated elements or application within disciplines), and how should we assess it?

Conclusions

A recently developed/formalized field, computational thinking is gaining widespread support as a core skill needed for full participation in a digital society as our world moves towards the Human-Technology Frontier. CT's rapid evolution has created challenges which, currently, are being

addressed world-wide through a decentralized system of research and development. These challenges include the evolution of a common definition of CT and agreement on various models of CT teaching, learning, and assessment. Although great gains have been made the past 15 years, much more needs to be done. In addition to developing a shared understanding of CT, comprehensively integrating CT into curricula, and rolling out/scaling CT efforts nationally, we recognize that in a rapidly changing world driven by technology we must find ways to speed the research/practice cycle to ensure that the skills/knowledge our students are learning in school today will advantage them in tomorrow's world. With increased opportunities for international networking and research/practice collaborations, together we can meet the challenges that rise from the global decentralized system of research, development, and practice of computational thinking.

Computer-Assisted Instruction, Changes in Educational Practice as a Result of Adoption of ICT

Rebecca Lai-wah Tam

Lancaster University, Lancaster, UK

Introduction

Over the last two decades, information and communication technologies (ICT) are becoming more and more important to organizations across the world. ICT for education has become increasingly influential nowadays, more than ever before. The adoption rate of ICT by higher education institutions has been rapid throughout the world, as tools for teaching, curriculum development, staff development, and student learning (Kumpulainen 2007; Usluel et al. 2008). Though ICTs are capable of improving the quality of teaching and learning, the benefits of ICTs are poorly conceived (Surry and Farguhar 1997). Not much is known about how computer systems affect learning (Koszalka and Ganesan 2004) or change in teaching practice (Becker and Jokivirta 2007). A critical review of existing literature on changes in educational practice is offered here, from a perspective of computer-assisted instruction (that, from the teachers' perspectives).

Generally, ICTs are developed to design, store, retrieve, and share information, as well as to communicate with peers, teachers, and other learning partners. ICTs are considered by Rouet and Puustinen (2009) as a means to implement different forms of constructivist, problem-based learning situations. It is becoming more and more important for education institutions to apply ICTs to facilitate learning, enhance teaching, and reduce educational costs (Pituch and Lee 2006; Selim 2007) so as to integrate ICTs in their instructional strategies. These approaches include delivering practice quizzes, lecture notes, other course materials, and announcements through web-based learning systems.

Changes in Educational Practice

Web-based learning (also known as e-learning) is defined as a learning process using web-enacting technologies to encourage interaction and communication between students and teachers (Gunasekaran et al. 2002). Various networking technologies (e.g., WebCT) and online resources are used as e-learning initiatives to support classroom-based learning and distance learning. Ngai et al. (2007) argue that web-based learning systems provide a platform to facilitate teaching and learning as well as new ways for conducting courses and distributing course materials. For years, web-based learning systems have been extensively adopted in education institutions. Changes in the educational practice are reflected in the perceptions of web-based learning systems which have been associated with interactivity, collaboration, and flexibility (Macedo-Rouet et al. 2009).

One of the major changes in educational practice is electronic delivery of lectures (also known as “e-lectures”). An e-lecture is not just a supplement of traditional teaching when a lecture was missed or for revision purpose (Brotherton and Abowd 2004) but also a means of distance learning (Mckinney et al. 2009). Besides using Microsoft (MS) PowerPoint presentations for delivering lectures (Fisher 2003), lecture audio recording software accompanied with MS PowerPoint slides are employed to form navigable “e-lectures” which makes the online lecture entirely available. More and more universities are adopting e-lecture recording technologies to solve web-learning problems (Rui et al. 2004). In fact, an e-lecture with interaction and navigation features has been found to yield better results when compared with a traditional lecture with the same content (Evans et al. 2004). Previous research shows that audio-visual synchronized presentations can be more effective than stand-alone MS PowerPoint presentations or audio files of the same content (Latchman et al. 2001). The work of Khadra et al. (1995) observes that students appreciate the opportunities and flexibility provided by e-lectures and the useful features of electronic learning tools. Other research studies

conducted by Tvedten et al. (1993) and Susskind (2004) also show that students prefer e-lectures. However, in comparing e-lectures with traditional lectures, the latter is more efficient, since the lecturer can keep more control over student learning by designing appropriate teaching strategies (Griffin et al. 2009) to deliver knowledge to a large group of students, although it is constrained by time and place.

Another major change concerns student engagement with web-based content materials which is highly facilitated by interactive multimedia (Kekkonen-Moneta and Moneta 2002). Past researchers observe that web-engaged students achieve high-order learning outcomes than face-to-face students (Maki et al. 2000). Students are pleased with web-based courses because of the interactive quizzes (Maki et al. 2000), interactive course content with self-assessment questions (Evans et al. 2004), and multimedia being more interesting than traditional lectures (Yazon et al. 2002). They perceive the web-based courses as more effective than the face-to-face courses. Several researches have concentrated on collaboration, for example, Oliver and Omari (2001) identify that web-based courses enable students to communicate with group members on aspects of problem-solving. Lockyer et al. (2001) argue that web-based courses allow keeping a record of discussion. Web-based learning motivates students to contribute more time in their learning, especially when the system creates possibilities for them to communicate with other students and teachers (Arulchelvan and Viswanathan 2006). However, web-engaged students have to adjust to a new learning experience when attending the web-based courses.

Despite the fact that web-based learning systems can be more effective and flexible than traditional approaches at imparting information (Holt et al. 2001) and do not hinder the learning process (Dewhurst and Williams 1998), the majority of students have a preference towards traditional approaches. As compared to a face-to-face course, students feel that more effort is required for learning in a web-based course (Maki et al. 2000). Lockyer et al. (2001) find that students are dissatisfied with the lack of

chances to ask questions and receive feedback from the lecturer in web-based environments. Though they realize that a web-based course is more effective than a face-to-face course, they still prefer the traditional face-to-face course. These students may well be those who are unfamiliar in using new technologies or they are accustomed to conventional teaching and learning approaches. Hence, students' adaptation to the e-learning environment becomes an issue that may affect their learning process. They need to use the Web to complete the learning activities and achieve learning outcomes and objectives (Ally 2002; Ritchie and Hoffman 1997). Thus, the changes in educational practice resulting from adoption of ICT are not without pitfalls.

Another major change focuses on the information system of web-based learning. Indeed, both teachers and students contend that information and communication technologies enhance learning (Lonn and Teasley 2009). The transmission of course materials and announcements is highly praised, as they help teachers to distribute information efficiently to students and promote communication between teachers and students. Similarly, teachers' teaching performance can be enhanced as a result of using the information acquired through web-based learning systems (DeLone and McLean 1992). Although with the help of the tools teachers save much time on information search, administrative work, and transmission of announcements, they can spend extra time in using the tools to develop more active learning (Herse and Lee 2005; West et al. 2007). The interactive tools enable students to read the online information in advance and be better prepared for discussion, analysis, and other learning activities. The tools help teachers to engage students in deep learning during class and extend the activities outside the classroom (Lonn and Teasley 2009). It was estimated in a recent survey that not less than 100,000 students in the United States use the Web for submission of their assignments (Bonham et al. 2003). Though it is evidenced that websites with information search features help students locate information and get better learning outcomes, few investigations have been done on the use of

web-based learning systems from an information system perspective (Pituch and Lee 2006; Toral et al. 2005, 2007).

Web-based learning systems facilitate not only the transmission of information but also the management and facilitation of student learning (Coaldrake and Stedman 1999). However, evidence of negative effects of web-based course delivery does exist. When students find it difficult to ramble through the course content on the Web, they lose interest in reading it (Evans et al. 2004). Despite the efficient information delivery, students prefer to print online materials even though they do not resist web-based courses (Bonham et al. 2003; Evans et al. 2004). In fact, they perceive printed notes as being faster to read, easier to annotate and highlight (Martin and Platt 2001), and can be carried anywhere (Martin and Platt 2001). Most probably students' choices of web-based resource are based on whether it provides them the highest possibility of passing the examination rather than it involving technology (Huon et al. 2007). In essence, students care about how Web tools are used rather than whether they are used or not (Holm et al. 2003).

Other negative perceptions of web-based learning systems relating to poor reliability of technology such as broken links, servers not responding, long download times, and insufficient access to computers have been observed by Oliver and Omari (2001). Students prefer using a table of contents to a Web menu as reading long texts on screen is tiring (Macedo-Rouet et al. 2009). They find it more difficult to understand long texts from screen than paper (Murphy et al. 2003). This finding matches with other research results on reading from screen (Eveland and Dunwoody 2001; Macedo-Rouet et al. 2003). Consequently, the increasing rate of users is not as fast as anticipated, though web-based learning systems are considered a useful tool for facilitating teaching and learning activities.

The last major change relates to the assessment features of web-based learning systems. Empirical evidence shows that a computer-based test is better than the paper version of the same test, though paper-based tests have been considered useful in education for a long time (Elton 1970). Clariana

and Wallace (2002) argue that paper-based and computer-based versions of the same test obtain different results. Tests that require organization of elements obtain higher scores with the computer (Threlfall et al. 2007). More exploratory trials can also be undertaken with computer-based test than on paper. However, the display of a computer-based test may require intensive interaction to switch between items, and increased cognitive load may lead to higher concentration on each single item (Macedo-Rouet et al. 2009). In terms of concentration, long reading comprehensive tests are deemed to be ineffective with the computer (Paek 2005). In summary, it has been concluded that different media afforded in tests may affect the performance.

Past studies attempt to find out whether web-based learning systems change teachers' pedagogical practice and students' preferences for how they learn. To enable institutional innovations in learning and teaching, more interactive forms of teaching and learning are essential for supporting constructivist-based learning (Dutton et al. 2003; Lipponen et al. 2004). Teachers have to learn how to use the tools and change their teaching practice to facilitate students' learning with those tools (Bender 2005; Gaensler 2004). When becoming familiar with the technology, teachers should use the interactive features more in their teaching practice to encourage active learning (West et al. 2007). Aiming at facilitating interaction among students, they should change their practice by avoiding immediate intervention in online discussions (Topper 2003). They should consider using reflective dialog such as writing prompts and teacher-supplied models of "good" messages to promote student engagement in reflection and discussion among themselves. Carmean and Haefner (2002) argue that web-based tools can encourage students to experience a deeper learning process by sharing their own representation of the new knowledge with their teachers or peers. Web-based learning systems act as an activator for self-reflection that helps to ease passive learning to become active (Herse and Lee 2005).

Improvements in the Quality of Teaching and Learning

Improvements in the quality of teaching and learning as a result of adoption of ICT depend on three apparent variables. These major variables include web-based learning design, pedagogic strategies, and computer literacy; these may contribute to better web-based learning performance through development of appropriate interactions with the learning environment (Freitas and Olive 2006).

Unlike traditional approaches, web-based learning can be student-centered, knowledge-centered, assessment-centered, and community-centered (Lowyck and Poysa 2001). The roles of teachers and students in this way have been changed. The teacher has become a learning facilitator with little (or less) control over students' learning behavior. Students' learning performance depends on their willingness to engage in active learning (Martens et al. 2004; Moreno and Mayer 2000). Despite the shortcomings of insufficient social presence or lack of verbal communication such as face-to-face responses (Francescato et al. 2006; Horn and Friedrich 2003) that have been remedied by audio-visual telecommunications such as Skype and MSN, students still lack incentives to participate actively in web-based learning that affects their performance (Horn and Friedrich 2003). To motivate students' learning, teachers need to include challenges for students, and means for cultivating cooperation and organizing the learning community in a web-based learning environment. Stimuli in the learning environment are considered as crucial to facilitate students' knowledge acquisition (Nonaka and Takeuchi 1995; Nonaka et al. 1998). It is concluded that the web-based learning design should include project-based and problem-based tasks or activities to stimulate student participation and active learning (Horn and Friedrich 2003; Pearson 2006).

To improve learning performance, a learning atmosphere should be created to encourage

students' engagement in collaborative learning. ICTs have enabled a collaborative learning environment at the expense of student motivation and engagement (according to Fu et al. 2009). Web-based learning can offer a productive learning atmosphere since collaboration among students becomes an effective learning strategy in the growth of knowledge. The learning atmosphere can encourage students to develop higher analytic and synthetic skills, thus constructing greater overall knowledge (Fu et al. 2009). Students' attitudes and achievements can be directly affected by the cooperative interactions among them (Rosenfield et al. 1981). Through manipulating pedagogic strategies, teachers can create an atmosphere with different degrees of social presence to achieve different degrees of learning enjoyment (Fu et al. 2009). Through the development of ICTs, a convenient and inexpensive online communication media is available. Unlimited resources can be made accessible online by teachers and students outside the courseware. If ICTs are used effectively, the web-based environment provides a high capacity for knowledge acquisition (Fu et al. 2009). However, students' computer literacy is crucial to effective collaborative learning. They must possess some prerequisite skills to enable them to complete web-learning activities. The less-skillful students should receive training before or during the learning process. In this way, students' computer literacy is considered as a variable influencing the effectiveness of web-based learning. Thus, teachers should always examine students' comfort and competence with the intervening technology and provide safe environments for them to increase their sense of computer literacy.

Conclusions

The adoption of information and communication technologies (ICT) has brought forth potential changes in educational practice – particularly in terms of computer-assisted instruction. These

changes can help to improve the quality of teaching and learning. Web-based learning systems can provide more reflective and useful interactions among students, teachers, and resources (Picciano 2002). ICT has assumed an enormous importance in improving the quality of education at all levels and has played a major role in educational endeavors towards enhancement as well as enrichment. Web-based learning systems provide a nontraditional learning and teaching environment. Different teaching strategies, activities, and technologies are used to create a dynamic learning community. A review of the literature suggests that integration of the new technologies and instructional strategies in education further enhances the quality, accessibility, and affordability of web-learning experiences.

Web-based learning delivery, depending on new technologies, has been largely enhanced. The challenge to practitioners is to explore what styles, strategies, methods, and activities are most effective, in terms of cost and learning, in developing and delivering quality web-based learning courses. As expected, web-based learning, similar to other forms of quality learning, being knowledge, community, assessment, and learner-centered (Anderson and Elloumi 2004), can enhance the important function of interaction in various ways among the participants. The task of the web-based course designer and teacher is to select, adapt, and facilitate educational activities that maximize the affordances of the web-based learning through feedback, assessment, and reflection. In doing so, they will help to create educational experiences that result in high levels of learning by all participants.

Synonyms

Computer-assisted instruction; Computer-aided instruction; Computer-based learning; Computer-mediated learning

This contribution explores computer-assisted learning (CAL) from a number of different angles. First, it discusses the many synonyms that exist for the use of information and communication technologies (ICTs) in education. Within these synonyms are concepts which often hide subtle but important differences from both a technological as well as a pedagogical/educational point of view. It proceeds with a short history of CAL. While CAL as an entity was first used in the early 1960s of the previous century (1960s), the concept underlying its use has roots dating back to the beginning of that century. The third and final part will focus on the effectiveness of CAL in education which will lead to an adaptation of the current definition.

What's in a Name?

In their *Dictionary of Computing*, Daintith and Wright (2008) describe CAL as

[a]ny use of computers to aid or support the education or training of people. CAL can test attainment at any point, provide faster or slower routes through the material for people of different aptitudes, and can maintain a progress record for the instructor. (Online entry)

This definition has changed through the course of time as the computer itself has changed from a bulky, building-large behemoth of tubes and wires to something that fits into your pocket and can be

even smaller. In the 1960s, computer use was first introduced in education. In this first phase of CAL, the computer was a mainframe which was connected to learners in specifically designed “classrooms” via terminals that were relatively far away from the mainframe computer. In this phase, the computer was primarily used as a knowledge-bank of questions which students could use for self-assessment of their knowledge. Using computers was extremely expensive and cumbersome and was only available for a “happy few.”

In the 1980s and 1990s, CAL was often used to refer to the development of either a single computer program or a series of programs which replaced more traditional methods of teaching. This was the direct result of the introduction in August 1981 of the IBM PC (personal computer) followed by the Apple II shortly thereafter. A mainframe computer was no longer needed to use computers for educational purposes and each student could work at her/his own PC in school or, for those pioneers, at home. This period also saw the introduction of what is now called computational thinking/coding with the launch of LOGO by Seymour Papert and his group at the Massachusetts Institute of Technology Artificial Intelligence Laboratory where, with the aid of PCs/microcomputers children in classrooms received an initiation to computer programming skills, turning it from an abstract activity only carried out by specialists into a concrete, real activity that could be carried out by students to program the movement of a robotic turtle.

This second wave was followed by a third wave ushered in by the introduction and availability of the Internet/World Wide Web where computers and people worldwide became connected to each other. This third wave also brought us tools such as email, webpages, blogs, etc. This broadened the concept of CAL to include, for example, web-based tools such as online learning environments, opening the door to online databases, making learning analytics a possibility.

The present wave is shaped by the availability of mobile devices (e.g., smartphones, tablets), semi-intelligent peripherals (e.g., augmented and virtual reality glasses, motion sensing input

devices, such as the Kinect or the Wii), and seamlessly integrated devices (e.g., the Internet-of-things) where CAL literally can take place any-time and anywhere where there is Internet (and that is virtually anywhere in the world).

Going back to Daintith and Wright's (2008) definition, when it is examined in detail one can distinguish a number of core elements:

- **Use of computers:** while there were analogue computers up to the 1960s, this now implies the use of many different digital media interconnected via the World Wide Web. To update this, it might be better to speak of the "use of multimedia and the Internet."
- **Support the education or training of people:** the "computer" will take up one or more roles and functions of the teacher and/or trainer to offer the learner necessary support and guidance during the instructional or learning event.
- **Test attainment at any point:** the "computer" will keep track of the learning process to determine whether the learner has achieved the goals of the CAL. It often does this by comparing the different products during the learning period with the beginning and end situations. This is related to what is now known as "learning analytics" which can be described as "the measurement, collection, analysis and reporting of data about learners and their contexts, for purposes of understanding and optimising learning and the environments in which it occurs." (Ferguson 2012, p. 305)
- **Provide faster or slower routes through the material for people of different aptitudes:** the "computer" provides possibilities to adapt the content of, pace of, and/or approach to learning based on learner progress which is presently determined by learning analytics. The terms now being used for this are adaptive learning and personalized learning.
- **Maintain a progress record for the instructor:** the "computer" is not only facilitated to let the technology adapt to the learner but also to inform the teacher/instructor to be able to adapt his or her approach based on the learning analytics.

Daintith and Wright (2008) also state that CAL is one of several terms used to describe this application of computers. Indeed, there have been many different names given to the use of ICT in education. Some names focus on the kind of technology being used, such as computer-mediated learning, computer-based learning, intelligent tutoring systems, web-based learning, and mobile learning. In these aforementioned cases, there can be an overlap between which technology is used and how the technology is used. And although the terms are often used as almost synonyms, at the same time it is perfectly possible to use mobile technology that is not web-based, to use computer technology that is not mobile or to use web-based tools that are not mobile or other web-based tools that cannot be used on personal computers.

The many names for the use of information and communications technology (ICT) in education can also hide differences between pedagogical and educational views, for example, the not so subtle difference between CAL and computer-assisted instruction (CAI). The difference between learning and instruction is the difference between a focus on the task of the pupil (learning) and a focus on the task of the teacher/teaching (giving instruction). This distinction goes far beyond the use of technology and has deep historical roots going back to the Romantic era (eighteenth century), but this does not mean they can be disregarded. Which name people use for the use of technology in education often discloses a certain vision on or philosophy of education. When using CAL, one comes close to a paradigm of social-constructivism where a pupil must build her or his own knowledge, while CAI could be regarded as a more cognitivist or instructivist approach which puts the emphasis on the need for an expert who can give the necessary support and guidance (Kirschner et al. 2006).

Finally, some of the names are a combination of the two. Take, for example, computer supported collaborative learning (CSCL). On the one hand, there is an emphasis on the technology, namely, the computer or, better stated, computers connected to each other through a network. On the other hand, there is emphasis on the pedagogy, namely, collaborative learning. This is an

approach to learning whereby a shift is made from learning individually and competitively to learning with others in the context of a team carrying out a task or solving a problem such that the members of the team share authority and accept responsibility for the group's actions.

The Pedagogical and Educational Roots, History, and Near Future of CAL

The oldest roots of thinking about machines helping someone to learn in a way resembling the definition of CAL date back to the first half of the previous century. Edward Thorndike (1912) was one of the first to think along the lines of *providing faster or slower routes through the material for people of different aptitudes*. He specified three conditions or laws that maximized learning. His law of *effect* held that the likelihood of a recurrence of a response is affected by reward or punishment. The law of *recency* held that the more recent something is, the more likely that it will recur. Finally, the law of *exercise* held that stimulus-response associations are strengthened through repetition. In his eyes, and based upon his laws, “[i]f by a miracle of mechanical ingenuity, a book could be arranged that only to him [*sic*] who had done what was directed on page one would page two become visible and so on, much that now requires personal could be managed by

print instruction” (p. 165). But Thorndike did not make such a – mechanical – learning machine himself. The first to do so was Sidney Pressey who developed a mechanical testing machine which he, oddly enough, called the *Automatic Teacher*. What it did was present students with multiple-choice questions, one at a time, that were sequences from least to most difficult. The student could only move on to the next question by answering the previous one correctly. This was intended to lighten the load on the teacher with respect to grading students so she/he could focus on more interaction with the student. While his machine was originally designed to make the testing and scoring of simple multiple-choice achievement tests possible, he soon discovered that it also had instructional qualities closely related to what later became known as programmed instruction as the device could show a predetermined sequence of questions one at a time, through an aperture. The student selected an appropriate answer from a card and pressed a key representing that answer; the selection of the correct answer resulted in the machine prompting a new question for the student (see Fig. 1).

After Pressey, more and different teaching machines were trialed and tested until in 1954 B. F. Skinner wrote his *The Science of Learning and the Art of Teaching*. In this seminal work, Skinner (1954) laid down the basics of his vision on programmed instruction which was then later

Computer-Assisted Learning, Fig. 1 Pressey's testing machine (https://en.wikipedia.org/wiki/File:Pressey_Testing_Machine_1.jpg; https://en.wikipedia.org/wiki/File:Pressey_Testing_Machine_2.jpg)

translated through different incarnations of teaching machines. The most important difference with Pressey's teaching machine – though similar to Thorndike's law of effect – was the strong emphasis that he placed on reinforcement during the learning process (Skinner 1961).

Skinner was inspired by the Socratic teaching method and, thus, he broke down complex lessons into a series of small questions. Each question required the student to respond to it in a way that built upon the correct response to the previous one. In this way, Skinner's machine (see Fig. 2) required students to master one concept before they were able to move onto the next, a type of learning that eventually came to be known as *mastery learning*.

Specific to all of these early teaching machines was their basis on a behaviorist view of learning (actually conditioning) where a stimulus is presented (a unit of preferably new information), a reaction (a response) is required, followed by immediate feedback as to the correctness of the response and which is often repeated to strengthen the connection. Arthur Lumsdaine (1959, p. 164), who researched the use of media and programmed learning, wrote that teaching machines have three basic characteristics:

- First, continuous active student response is required, providing explicit practice and testing of each step of what is to be learned.
- Second, a basis is provided for informing the student with minimal delay whether each

response he makes is correct, leading him directly or indirectly to correction of his errors. Third, the student proceeds on an individual basis at his own rate – faster students romping through an instructional sequence very rapidly, slower students being tutored as slowly as necessary, with indefinite patience to meet their special needs.

The devices thus represent a way of providing a preprogrammed study-practice combination which simulates, in partially or fully automated fashion, the functions of a private tutor in recitation and practice, with immediate correction of errors and feedback to the student.

This first phase of learning machines can be regarded as the behavioristic phase. Though different forms of “computers” were around long before the 1960s – the Antikythera mechanism, for example, has been described as a computer from ancient Greek times (Freeth et al. 2006) – and there have been different learning and teaching machines, the concept of “computer-assisted learning” stems, as stated, from the 1960s of the previous century. While scientific references are older (e.g., Coulson et al. 1962; Glaser 1965; Suppes 1965), the first real mentions of CAL in scientific journals can be found in 1966, after its mention at conferences in 1965 (e.g., The Conference on Computers in Physics Teaching, University of California at Irvine, November 1965) (Based on searches in ERIC and Scholar which resulted in Fowler (1966), Hirsch (1966), and Trump (1966) as oldest sources).

Computer-Assisted Learning,

Probably due to a combination of resources, perceived affinity of the domain for CAL and political forces that often drive changes in education, the natural sciences (including mathematics and medicine) were the early adopters of CAL. A good overview of this can be found in a special issue of *Computers & Education* in 1992 (volume 19, numbers 1–2). For example, the integration of the computer into medical education was recommended in 1979 by Daniel Tosteson, then Dean of Harvard Medical School, when he proposed that the use of what he called “information-processing devices” be developed as a core component of the medical school curriculum. Michael Hewson, in his seminal work on the use of microcomputers in science education (1984) summed it up as follows: in science education, microcomputers allow students to play a more active role in learning, get individual attention for their specific difficulties, and allow students to control the pace at which they work. Also, physics educators showed a particular interest in CAL (e.g., in Fowler (1966)). Another specific form of CAL, computer-assisted language learning (CALL) stems from the same period (Marty 1981), though the use of computers for language learning was at first limited to universities. CALL makes use of computer technology to aid in the presentation, reinforcement, and assessment of language material – usually a second or a foreign language – to be learned. While originally based upon stand-alone applications on microcomputers, CALL now uses a broad range of technologies and approaches ranging from traditional drill-and-practice programs to virtual learning environment and web-based distance learning with its most recent being mobile-assisted language learning (MALL; Shield and Kukulska-Holme 2008).

After these initial often behavioristic inspired approaches of CAL – see also the link with Skinner and Thorndike – in the 1970s and 1980s a different approach to CAL and CALL could be seen with more Intelligent Tutoring Systems introducing a second rather cognitivist phase. The advocates of this approach argued that all CA(L)L courseware and activities “should build on intrinsic motivation and should foster

interactivity – both learner-computer and learner-learner” (Han 2009, p. 41). In this cognitivist phase, research and development now were directed at finding, studying, and implementing methods and strategies that would bring about specific and desired cognitive processes, for example, assisting learners in selecting information, organizing it into internally consistent concepts, and integrating new with existing knowledge in cognitive schemata so that it would be personally relevant and meaningful. This second phase coincided with the second wave discussed earlier that came from outside education as, from the 1980s onwards; the microcomputers made computer technology more accessible to a broader audience and to educational institutes besides the universities. Warschauer and Healey (1998) describe a third phase as social-constructivist with a strong emphasis on agency (Warschauer 2000). But it can be argued that for this objective of agency, a democratization of microcomputers was not enough; the third wave described as integrating the worldwide web was key for this.

A fourth phase benefited also from the technological evolutions which came with the development of network-based technology, through which people can share whatever and communicate with each other whenever and wherever (Tafazoli and Golshan 2014), which made an evolution possible from a social-constructivist approach to a connectivist approach. This phase coincided with computer technology becoming more mobile, which led to mobile devices such as laptops, smartphones, iPads, and Augmented Reality-devices, with the possibilities of a steady growth of computing power, making it possible to handle large amounts of data, now referred to as Big Data, or as we call it today in education: learning analytics. These kinds of mobile devices, combined with technology as the original definition stated that is able to *test attainment at any point*, can give the user both teacher and learner agency.

A further evolution of CAL can come in the form of the use of artificial intelligence (AI), with smart assistants helping both teachers and students in their teaching and learning process. A

first example was delivered by “miss Jill Watson,” an AI-assistant powered by IBM’s supercomputer Watson that answered email-questions of students of Professor Eric Wilson (Korn 2016).

The Effectiveness of Computer-Assisted Learning

The first law of Kranzberg (1986) states that “technology is neither good nor bad; nor is it neutral.” This is also the case when discussing the effectiveness of CAL. In 2015, the OECD (2015) concluded that more computers do not necessarily mean more learning; it is more important to see how the technology is being used. In his review of the many different meta-analyses on computer-assisted instruction, John Hattie (2009) described a reasonable degree of variability across the overall effect sizes. The advice Hattie gives is that the use of computers is more effective when:

- There is a diversity of teaching strategies.
- There is teacher pretraining in the use of computers as a teaching and learning tool.
- There are multiple opportunities for learning (e.g., deliberative practice, increasing time on task).
- The student, not the teacher, is in “control” of learning.
- Peer learning is optimized.
- Feedback is optimized.

In other words, it is the pedagogy and not the technology that can affect outcome. This is an echo of Richard Clark (1983) who found that research on media showed that when differences between media on learning are found, it is the method that causes the difference and not the medium. He summed this up in his famous quote, “[M]edia are mere vehicles that deliver instruction but do not influence student achievement any more than the truck that delivers our groceries cause changes in our nutrition” (p. 445).

A more recent literature-review for The National Bureau of Economic Research by

Escueta, Quan, Nickow, and Oreopoulos discusses the evidence to the present time (2017) on the use of technology in the classroom. For their review, the authors compiled publicly available quantitative research that used either randomized controlled trials or regression discontinuity designs (where students qualify for inclusion in a program based on a cut-off score at pretest). All the studies that were used in the working paper examined the effects of an educational technology intervention on any education-related outcome, which makes this work broader than studies only looking at a learning effect. The working paper included not only the areas of technology access, computer-assisted learning, and online courses but also the less-often-studied technology-based behavioral interventions.

What are the conclusions?

- Access to technology may or may not improve academic achievement at the K-12 (4 to 6-year-olds through 12th grade (12) for 17 to 19-year-olds) level, but does have a positive impact on the academic achievement of college students.
- Online learning courses had the least amount of research that could be examined and showed the least promise of the four areas. However, when online courses were accompanied by in-person teaching, the effect sizes increased to scores comparable to fully in-person courses.

But the most relevant conclusion of the paper was that:

- Computer-assisted learning, when equipped with personalization features, was an effective strategy, especially in mathematics (Escueta et al. 2017).

This last conclusion means that one element of the definition of CAL is key for its effectiveness: *Provide faster or slower routes through the material for people of different aptitudes*, although personalization can go much further than adapting the speed of the learning routes; in this regard, the 2010 National Educational Technology Plan (Office of Educational Technology 2010)

describes personalized learning as “broader than just individualization or differentiation in that it affords the learner a degree of choice about what is learned, when it is learned and how it is learned; this may not indicate unlimited choice, since learners will still have targets to be met.” This element of personalization, its role in effectiveness of computer-assisted learning, and the new possibilities from technology have warranted an adaptation of the definition by Daintith and Wright. A possible amendment could be the following (the modification is in *italics*):

Any use of computers to aid or support the education or training of people. CAL can test attainment at any point, *personalise the learning routes both in speed, complexity and other possible forms of personalisation of learning*, and can maintain a progress record for the instructor.

Conclusion

Computer-assisted learning (CAL) is older than one may think, dating back to the early 1960s of the previous century, with roots dating back to the beginning of the previous century. The meaning and focus of CAL has changed throughout time, shifting from behavioristic, through cognitivist and social-constructivist to connectivist visions, often fuelled by technological evolutions. While many people have put hope in technological breakthroughs making it possible to have better learning results, the actual research shows mixed results.

Introduction

This entry explores computer-based learning (CBL) designs that are informed by the learning theory of constructionism. First, it discusses different definitions and types of CBL and explores the pedagogical approaches that underpin CBL designs through a brief history of CBL

in education. Next, it elaborates on the role of the constructionist paradigm in CBL and presents different CBL designs that are based on constructionism. Then it focuses especially on the use of constructionist CBL approaches for supporting students to cultivate their computational thinking. The final part discusses the educational challenges and the near future of constructionist CBL.

What Is Computer-Based Learning?

Computer-based learning (CBL) is a term that is used to describe “any use of computer software for the purposes of supporting the process of learning” (Adams 2004). Similarly, the term computer-based learning environment (CBLE) refers to the software that students use and interact with during CBL, and it includes any computer application, tool, or program that is developed and designed to support the learning of a specific subject.

CBL focuses on the individualized self-study of a learner through his/her active engagement in a set of digital activities designed with a pedagogical agenda. Usually, CBL implies the absence of a teacher or a facilitator during the learning process. This doesn’t mean, though, that it is necessarily implemented out of school. In many cases, CBL takes place in the classroom context as part of the curriculum supplementary to teaching (Serin 2011; Adams 2004; Valdez et al. 1999).

Interactivity is a core characteristic of CBL that distinguishes it from other educational media like presentations, video and audio, etc. The learner interacts with the digital learning environment, which responds with feedback, leading to iterative cycles of practice and reflection. In order to support different types of learners, CBLEs are usually designed to provide multiple forms of interdependent representations along with the presentation of information and activities in a nonlinear format. In the literature, we find different categories of CBL according to the type of technology that the learner uses and the level of interactivity between the learner and the digital environment. Some common categories that we find in the literature are the following (Adams

2004; Hackbarth 1996; Serin 2011; Valdez et al. 1999):

- *Drill-and-practice*. Learners answer successive short questions and quizzes. They have to answer correctly each question to progress to the next one; otherwise, they repeat it. This type is usually used to teach segmented content through memorization.
- *Tutorial*. It is similar to drill-and-practice, but it contains more information and educational material. Learners follow a step-by-step guided instruction that provides them with information, examples, and exercises for practice, in order to acquire satisfactory knowledge of specific concepts or skills. In some cases, it is used as a replacement for teaching while in others as a supplement to enhance a student’s knowledge in a certain area.
- *Inquiry*. Learners use digital tools such as databases, spreadsheets, etc. to search, acquire, and synthesize information on a specific subject. This type of CBL engages learners not only with the acquisition but also with the assessment of digital information.
- *Simulation*. Learners explore a real-world phenomenon that is simulated with a model in the digital environment. As they interact with the model and observe the results, they discover the rules, relations, and concepts that underpin the behavior of the simulation. Simulations are usually used in the classroom with the teacher intervening to explain concepts, ask questions, and draw the attention of students to specific points of the model.
- *Programming*. Learners use a programming language to solve a computational problem or to create a digital artifact (i.e., a game, a drawing, etc.).
- *Educational games*. Learners play a digital game that is pedagogically designed to integrate scientific concepts. While they play, learners discover and use concepts and skills through a meaningful and motivating experience for them.

An important element of CBL mainly afforded in the first two categories is the

adaptability to the learner's needs (Moos and Azevedo 2009). In these two categories, educators may use CBL in the classroom for various purposes including (Moos and Azevedo 2009) increasing the productivity of student class work, fostering student interest and motivation, personalizing the learning process, etc. According to different reports (Serin 2011; Moos and Azevedo 2009), possible benefits that CBL can add to the learning process are:

- (a) Enabling students to progress at their own pace by individualizing the learning process (mainly regarding the first two categories).
- (b) Motivating students to participate in the learning process by providing them with a familiar and attractive context.
- (c) Supporting students' self-evaluation and self-reflection by providing immediate feedback.
- (d) Students may connect scientific concepts to their daily lives and their interests.
- (e) Students are actively engaged in the learning process and construct knowledge.
- (f) Apart from the construction of knowledge, it can also help the development of creativity and problem-solving skills.

However, according to studies, the effectiveness of CBL varies between individuals and between different CBLEs. Factors that may affect the learning outcomes of CBL are the personal characteristics of each learner (Moos and Azevedo 2009), like self-efficacy, experience, and prior knowledge, but also the affordances that the learning environment provides to the learner for interaction and active engagement.

Each category of CBL follows a different pedagogical approach and utilizes diverse types of technology. Ellington et al. (as mentioned in Adams 2004) describe three pillars that form a CBL design: (a) the *hardware* that refers to the actual computer and its specifications; (b) the *software* that refers to the computer application or program that is used; and (c) the "underwear" that refers to the pedagogy on which the CBL is grounded. The latter one affects the design of the computer-based learning materials and the level of interactivity that the environment provides to

the students. Since the first use of computers for educational purposes in the 1970s, all three pillars have evolved, and so has CBL.

A Brief History of the Pedagogical Paradigms of CBL

The term CBL was first introduced in the 1970s as an approach of integrating computers in education with the role of tutors, as in the first two categories in the previous section. Back then, personal computers provided the user with very few functionalities due to the technological limitations of that era. The first educational software was mostly textbooks presented in electronic formats like tutorials and drill-and-practice programs that aimed to teach specific scientific concepts to students (Adams 2004; Hackbarth 1996). The design of CBLEs was program-centered and instructionist. They usually provided students with pre-defined educational content structured in a linear way, allowing limited control and interaction to the learner. The dominant pedagogical approach that underpinned CBL designs at that time was *behaviorism*, which focused on breaking learning into small achievable steps, with students having to master each one sequentially (Adams 2004; Valdez et al. 1999).

Technological developments that followed led to a new paradigm for CBL that emerged from cognitive psychology. The revelatory paradigm, as it is called by Adams (2004), is based on *discovery learning*, and it promotes students' exploration and discovery of rules, laws, and relationships in a given simulation or model. Cognitive approaches to CBL emphasize how students know rather than how they respond, and they focus on the development of higher-order thinking and problem-solving skills through planning, analyzing, and communicating.

In the early 1970s, Seymour Papert together with Feurzing built the Logo programming language and introduced the Turtle Geometry learning environment to mathematics education (Papert 1980). The Logo language made programming accessible to every child in the form of an expressive medium with which to do

mathematics. However, it was not until the early 1980s that schools started to integrate Logo programming into their curricula. During the 1980s, many schools showed great enthusiasm for teaching their students mathematical and programming concepts with Logo. Together with the spread of Logo programming in schools, an epistemological approach called *constructionism* was developed by Papert, resulting in a number of new approaches to CBL.

However, by the late 1990s and early 2000s, many schools turned away from programming, mainly because of a lack of subject-matter integration and a lack of qualified instructors (Noss and Hoyles 1996). When software tools with dynamic manipulation and icon-driven technology appeared, programming was seen as a kind of unnecessary noise when compared to doing interesting things with digital media (Kynigos 2015). As a result, CBL environments started to use hypermedia and interactive visual technologies to attract students, leaving aside the constructing part.

During the last decade, however, we are facing a comeback regarding the interest in programming as a means of expression (Kafai et al. 2014) and of constructionist CBL designs. This time, programming is considered an integral part of a new perception of computational literacy. Recently, renewed perceptions about the value of computer programming have become popular; that every child can and should learn to write code as a way to develop their computational thinking. The idea of computational thinking that Wing described in 2006 as “a set of thinking skills, habits and approaches that are integral to solving complex problems using a computer and widely applicable in the information society” is now considered as a necessary expressive skill for twenty-first-century students (Kafai et al. 2014; Lee et al. 2011). In this context, constructionism has a lot to offer both as a pedagogy that underpins computer-based activities and as a theory of design (Kynigos 2015) that guides the development of new computer-based learning environments.

Constructionist Approaches to CBL

Constructionism endorses the main principles of the constructivist learning theory; that knowledge is not determined information communicated from a transmitter (i.e., teacher) to a receiver (i.e., student), but it is actively constructed by the learners according to their own experiences and interactions with the world (Papert 1980; Ackermann 2001; Kynigos 2015). Cognition is adaptive, and conceptual changes may emerge as a result of the learner’s evolving organization of the experiential world.

Constructionism shifts the focus from understanding the conceptual changes that occur at different stages in the life of the learners to the actual meanings that the individual learner generates in specific contexts (Kynigos 2015). It emphasizes on how the learner forms, communicates, and reforms meanings and powerful ideas while he/she interacts and constructs artifacts with digital tools. For constructionism, *a key concept in learning is the expression of personal feelings and ideas* (Ackermann 2001), and digital media are one of the means to support this expression through different representational forms. With the mediation of digital technology, students can access and explore some very *powerful ideas* which, with other means, would be inaccessible or difficult to understand (Papert 1980).

In constructionist approaches to CBL, the software and its affordances become tools for the learner to construct with and “objects to think” with (Papert 1980). In that context, the aim of CBL is not to transfer the knowledge from the computer to the learner, as happened with the behaviorist approaches, but for the learner to produce the knowledge using the computer as a tool. Constructionist CBLEs are designed to provide the learner with the appropriate affordances to access powerful ideas and enable actions like building a model, reflecting on it, and sharing the model with others (Noss and Clayson 2015).

Constructionism was initially perceived as an approach to an experiential learning process of the individual, or at least without much emphasis on

interaction between humans. Papert himself, however, elaborated on the process and the value of a learner publicizing their construction before it was considered a final artifact, in order to share and discuss its features and properties during the process of improving or changing. It was this discursive aspect that gave rise to a socio-constructivist approach to constructionism elaborated by other researchers such as Kafai et al. (2014). In constructionist approaches, the sharing of the constructed artifact in a community is as important as its construction, as it affects a learner's understanding and generation of meaning. Based on the Vygotskian sociocultural perspective of learning, Borba and Villarreal (2006) developed the "Humans-with-media" approach to describe how the engagement with a task through digital media can create and transform collectives of learners which affect the reorganization of thinking and the generation of meaning of the individual learner. According to their view, digital media result in dialogue and discussion about the learning task, leading the learner to reform his/her understanding and to reengage with the task from a newly situated perspective. In that sense, digital technology has a mediating role to thinking, similar to the one that language has in Vygotsky's approach. This social aspect of the learning process underpins many designs of CBL environments, which emphasize sharing, exchanging, and evaluating the constructed artifacts with digital media.

Noss and Clayson in their article "Reconstructing Constructionism" describe six characteristics of a constructionist design agenda that should underpin computer-based learning environments. The first is the idea of *modelling*, referring to the process of building, reflecting, and debugging, through which learners can develop internal knowledge structures about powerful ideas. The second is the provided *accessibility* to the modelling process so that the learners are aware of the existing models and how they are created. The third is the *layering* of scientific concepts by integrating increasing problem-solving complexity into the learning

environment. The fourth characteristic is to carefully design a digital environment that is *aligned with the learners' agenda and culture*. The fifth is the *representation of the knowledge* in a language with which learners can express themselves. And finally, the sixth characteristic is to promote *collaboration* by enabling learners to share artifacts and ideas and to communicate both in the same space and at a distance.

In the next section, five constructionist CBL approaches that integrate all or most of the above elements and have been implemented and studied in a classroom context are described. For each one, examples of widely used CBLEs and relative studies with students are presented.

Microworlds

One of the first constructionist approaches used in CBL designs was the idea of microworlds. Papert (1980) introduced the term microworld to describe a digital artifact "designed to invite engagement in the activity, ownership of ideas and learning style and exposure – i.e., expressing one's own ideas to others – for exploration, negotiation and communication" (Healy and Kynigos 2010). A microworld simulates a real-world situation or phenomenon and provides students with functionalities to explore, change, and extend the initial rules and behaviors of the simulation. As we read in Balacheff and Kaput (1997), there are two basic features that constitute a microworld:

- (a) *A set of primitive objects, elementary operations on these objects, and rules expressing the ways the operations can be performed and associated.*
- (b) *A domain of phenomenology that relates objects and actions on the underlying objects to phenomena at the "surface of the screen." This domain of phenomenology determines the type of feedback the microworld produces as a consequence of user actions and decisions.*

Microworlds allow learners to use and modify their rules and objects and to create new ones. Thus, the learners have simultaneously the roles of user and designer. The first microworlds focused mainly on the exploration of

mathematical concepts with the use of the Logo programming language (Papert 1980). In the following years, students of different ages in many schools programmed, explored, and changed mathematical models in microworlds designed with the Logo language or with other Logo-based languages like StarLogo (Resnick 1997; Noss and Hoyles 1996). The relative research showed that the characteristics of the Logo language combined with the representational structures provided by a microworld facilitated students' meaning generation about complex mathematical concepts and ideas (Papert 1980; Kynigos 1995). Until today, the microworlds approach has a significant impact on CBL for mathematical education.

The idea of the microworld associated with Logo Geometry evolved over the years, along with the technological advances of software and hardware. Today, there are a number of online authoring systems for designing, using, and sharing mathematical microworlds. Some of them, like GeoGebra 3.0 (<https://www.geogebra.org/>) and Cabri Géomètre (<https://cabri.com/en/>) (Balacheff and Kaput 1997) environments, provide the learner with a number of visual tools instead of programming, while others integrate programming with computational affordances such as dynamic manipulation (Fig. 1). For example, Machine Lab Turtlesphere 2 (MaLT2; <http://etl.ppp.uoa.gr/malt2>) (Kynigos and Grizioti 2018) is an online environment that combines Logo-

based programming with dynamic manipulation and 3D navigation for the exploration of mathematical concepts. Despite their strong connection with mathematics education, microworlds have also been used in CBL activities for other scientific domains, such as physics, engineering, and history (Healy and Kynigos 2010).

Kynigos (2007), based on the idea of microworlds, coined the term “half-baked microworlds” which refers to “fallible artifacts” pedagogically engineered so as to have one or more “buggy” behaviors built into them. The aim of these “bugs” is to provoke students to fix them in order to improve the original artifact. One characteristic example is the half-baked micro-experiment “Help Yiannis fix a bug” developed in the authoring system MaLT2 (Kynigos and Grizioti 2018). The term micro-experiment refers to a microworld that has a much more focused problem comprising of a set of closed questions and only ending up with an open question leading to investigation. For instance, the micro-experiment of Fig. 2 contains a Logo code that constructs a “broken” parallelogram, and it asks students to inspect the code, identify the bug, and fix it, thus looking deeply into the properties expressed with the buggy code. The concept of micro-experiments was coined by Kynigos and Grizioti (2018) as an approach to reach a larger number of teachers and students in the classroom, attempting to increase the scalability of the MaLT2 environment in the formal educational system.

Agent-Based Modelling and Simulations

Agent-based modelling is a CBL approach that is usually used for simulating complex phenomena with multiple, interacting digital agents. In such models, the learner specifies the behaviors, interactions, and rules between the agents and observes the emergent outcomes in the system. Agent-based modelling has been used in educational contexts for diverse domains such as biology, mathematics and probability, programming, economics, and urban planning. Today there are a number of agent-based environments that are used for designing models and simulations of scientific or social phenomena.

For example, NetLogo is an agent-based modelling environment that is widely used in school contexts (Wilensky and Resnick 1999). Students can control thousands of independent agents, called “turtles,” which they all operate simultaneously (Fig. 3). This enables the exploration of the phenomenon in two levels: (a) in a microlevel, regarding the connections, behaviors, and interactions between the agents, and (b) in a macro-level regarding the patterns and the results that emerge from these interactions in the whole system.

Simulation models developed with NetLogo are based on the idea of “thinking in levels.” The notion of levels focuses on the investigation of how complex phenomena can arise from simple components and simple interactions (Wilensky and Resnick 1999). The agent-based computational representation of otherwise complex phenomena is a form of what Wilensky and Papert (2010) called “restructurations.” They considered restructurations as “reformulations of knowledge disciplines through new representational and communicational forms.” In simulations of NetLogo, the computational objects (agents) replace more traditional representations of a phenomenon (i.e., algebraic). These objects have cognitive, social, and affective properties that make complicated topics accessible and learnable by a much wider and younger population (Wilensky and Papert 2010).

Another example of an agent-based modelling environment is AgentSheets (<http://www.agentsheets.com/>) (Ioannidou et al. 2009). In AgentSheets learners can create agent-based simulations, using its end-user programming language Visual AgenTalk (VAT). They can build rules for the agents’ behavior by combining

Computer-Based Learning, Computational Thinking, and Constructionist Approaches, Fig. 3

A simulation of an ecosystem of wolves and sheep created with NetLogo

conditions and actions from special command palettes. The commands are pre-defined and limited in number which makes the environment easily accessible by people with no previous experience in programming. However, this may also have some limitations regarding the expandability and complexity of the simulations that one can design, lowering the ceiling for the experienced users. AgentSheets has been used in schools mainly as a tool for designing simulation and games in a variety of domains including computer science, environmental design, fine art, robotics, music, history, and biology.

AgentCubes (<https://agentcubesonline.com/>) is another version of AgentSheets that enables the design of three-dimensional (3D) games and simulations (Ioannidou et al. 2009). The additional feature of 3D allows for exploration of more complex phenomena and representations in space, raising the ceiling of the AgentSheets version. The environment includes rich media such as audio and 3D models, a 3D environment with layers and camera controls to switch perspectives. The programming of the game or simulations still follows the rule-based approach, in which the user

combines ready-made commands of VAT language provided in command palettes. AgentCubes has been used in the classroom mainly as a tool for the incremental development of students' information technology (IT) skills and computational thinking.

Logo-Based Coding Environments

Even though programming is by itself a type of computer-based learning, not all programming CBL activities are informed by the constructionist approach. For instance, many programming exercises are closed quizzes and puzzles with only one correct answer and with the "making" element being quite limited. In coding learning environments that implement the principles of constructionism, programming is seen as a means for construction and expression of personal ideas, aiming to lead students to the generation of meaning. Thus, the learning activities are based on exploration, building, and testing, sometimes following a model of gradual engagement with the construction.

The earliest example of a constructionist coding environment was Papert's Logo Geometry

in which students wrote commands in Logo language (forward 100, left 90, etc.) to control a moving “turtle” which drew on a canvas as it moved (Papert 1980). Logo programming has been used in CBL for engaging students not only with programming concepts but also with mathematics, physics, arts, and many other domains.

Today there are a number of Logo-based coding environments used in CBL that are aligned with new technological developments (i.e., online access, 3D graphics, etc.). They are all based on the Logo Geometry philosophy, programming a moving avatar that draws on a canvas, but they usually implement different versions of the original Logo programming language, and sometimes they integrate additional functionalities. For example, Turtle Academy (<https://turtleacademy.com/>) provides a number of online lessons with Logo Geometry that run directly on the browser. In addition, it has a “playground” mode for experimenting freely with Logo programming. The context of the lessons and the graphics of the environment resemble the classic Logo Geometry microworld of Papert.

Another Logo-based online environment is MaLT2 (<http://etl.ppp.uoa.gr/malt2/>) (Machine Lab Turtlesphere 2) (Kynigos and Grizioti 2018) developed by the Educational Technology Lab team of NKUA. MaLT2 allows the creation, exploration, and dynamic manipulation of 3D geometrical models with textual programming. MaLT2 implements Logo programming, based on Brian Harvey’s Berkeley Logo, and extends it with the integration of three affordances: (a) 3D drawings, as the avatar moves in three dimensions (x, y, z); (b) dynamic manipulation of any model that has been created by a parametric procedure; and (c) free navigation in the 3D space with a periscopic camera that allows observation of the model from different points of view. MaLT2 has been used in the context of mathematics and computer science education in several schools in Greece and for the development of 240 micro-experiments uploaded in the digital portal of the Greek Ministry of Education (<http://dschool.edu.gr>), one of the most visited sites in the country.

Some constructionist coding environments use visual programming languages instead of

textual programming. Visual programming, like block-based languages, can be beneficial for younger or inexperienced students by decreasing the learning curve of the language and the number of syntax errors that novice programmers usually make.

Scratch (<https://scratch.mit.edu/>) is probably the most popular visual programming environment that is widely used in CBL in the classroom. Scratch was developed by the MIT media laboratory team, and it provides a collection of graphical “programming blocks” which users can snap together to create programs. These blocks are shaped to fit together only in ways that make syntactic sense (Resnick et al. 2009). The Scratch environment and its programming language are based on the idea of Papert’s Logo Geometry; thus every command has visual results on a 2D canvas. Similar to Logo Geometry, the user can program an avatar that moves and draws on the canvas. Apart from that, the environment supports a number of diverse features, like creating and controlling multiple avatars, creating an animation of the same avatar, adding sound and video, and more. The large number of programming options (divided into block categories) allows for the creation of a large variety of projects, from drawings to games and from animations to greeting cards (Fig. 4).

Scratch, apart from being a tool for CBL, also has a large online community in which teachers, researchers, and students create, share, evaluate, and remix Scratch projects on the web. Since the public launch of Scratch in 2007, millions of students around the world have used it to construct their own interactive stories, games, and animations – and share their creations with others. Today, Scratch has been integrated as a suggested coding environment in computer science curricula of many different countries, and it has been translated into more than 70 languages. In addition, a large number of studies have shown its benefits in the development of students’ IT skills, motivation, design skills, and computational thinking skills. However, some researchers have criticized Scratch, and block-based programming in general, for lowering the ceiling of the programming process and having significant limitations

Computer-Based Learning, Computational Thinking, and Constructionist Approaches, Fig. 4 The CBLE of Scratch

compared to text-based programming environments (Grover and Pea 2013). For instance, Scratch does not support the creation of functions, which is a core element of procedural programming. A new environment called “Snap!” that allows the creation of new Scratch Blocks could possibly be a way to address this issue.

Other online visual programming learning environments that implement Logo Geometry include BeetleBlocks (<http://beetleblocks.com/>), which integrates block-based programming and 3D Logo Geometry, and Pencil Code (<http://pencilcode.net/>) that provides the opportunity to switch between block-based language and JavaScript. However, they have not yet been used as tools for CBL activities in the classroom context.

Game Design Environments

Children today spent a lot of their time playing video or mobile games, so game design activities

can be quite motivating and interesting to them. In game design with computer-based learning activities, students explore ideas about one or more domains by designing a digital game in a learning environment. Constructionist game design environments provide students with powerful tools to build, test, and share their own digital game, giving them the role of both the player and the designer of the game. The CBL environments usually include programming, but they may also integrate additional affordances like a text editor or a graphic designer.

In game design activities, students have to deal with a complex interactive system (the game), the design of which requires system-based thinking and iterative problem-solving (Salen 2007). According to Salen, students as game designers are engaged in a cycle of iterative playtest, evaluation, and modification of the game system. In order to create a functional, meaningful, and attractive game, they get involved with complex

Computer-Based Learning, Computational Thinking, and Constructionist Approaches, Fig. 5 Alice 2.0. CBLE

processes and decisions, such as writing the script, programming the rules, creating the characters, and making artistic and aesthetic choices. During these processes, students usually apply high-order skills and also knowledge from different domains. Thus, game design has been used in the CBL of diverse school subjects such as computer science, physics, engineering, history, and also for multi-disciplinary learning.

One widely used game design platform is Alice (<https://www.alice.org/>), a visual programming environment with 3D interactive graphics, where students can control the behaviors and rules of 3D objects by writing simple scripts. Its visual programming language provides the user with a number of built-in actions that can be used either to program the behavior of objects (e.g., move, turn, roll) or to change the physical nature of an object (e.g., resize, hide, etc.). It also allows users to create new functions, a feature that gives extensibility to the original language and a high ceiling to the tool. The new version of the learning environment (Alice 3) maintains the features of previous ones but adds emphasis on object-oriented

concepts. Since the early 2000s, Alice has been used in several middle schools and high schools, mainly as a CBLE for the subject of computer science. Relative research (Werner et al. 2012) has shown that Alice can be a powerful tool for introducing programming to young students as it allows them to focus on problem-solving skills instead of spending time on syntax errors, compilation errors, and environment set-up problems (Fig. 5).

Gamestar Mechanic (<http://gamestarmechanic.com/>) is another CBL environment for game design that aims to provide young children with “a platform on which they can build technical, technological, artistic, cognitive and social skills suitable for our current and future world” (Salen 2007). In Gamestar activities, students can have different roles. They can be players, designers, reviewers, and modders of games. They can also share their games in the online community of Gamestar and comment on each other’s games. Gamestar also provides a number of resources for teachers to implement in their classrooms, including single-session activities and long-term

curriculum. Gamestar has been used for teaching concepts from different domains including game design, science, arts, and science, technology, engineering, and mathematics (STEM) education.

In studies with Gamestar Mechanic (Salen 2007), researchers applied the method of game modification to introduce students to the elements of the game and the game principles. They designed small challenges of increasing difficulty to scaffold students' engagement through progressive modifications. The studies showed that game design increased students' motivation to participate in computer programming and their interest remained high throughout the activity. In addition, their studies suggest that game design can help students cultivate skills such as creative problem-solving, writing and storytelling, IT skills, and critical thinking.

Integrated Affordances

An important element in CBL is the affordances of the learning environment and the way that students use and combine them to construct knowledge. In the context of a digital learning environment, affordances are considered as the opportunities that the environment offers to the learning process by enabling a number of actions to the student. The way that students would perceive and utilize the affordances depends on their existing knowledge structures and experiences, and as their knowledge evolves so may their perceptions of the environment's affordances. In constructionist learning environments, the affordances are formed by the available tools and functionalities for construction but also by the behaviors and interpretations that students may assign to the tools while they use them. Thus, the type of integrated tools in a learning environment and the way that they are connected with each other by design can play an important role in CBL.

Aiming to extend the idea of scaffolding, Noss and Hoyles (1996) introduced the term "webbing" to describe "a structure that learners can draw upon and reconstruct for support in ways that they choose as appropriate for their struggle to construct meaning." The webbing notion builds

on the perception that learning is the construction of a web of connections of scientific ideas including connections between classes of problems, between mathematical objects and relationships, etc. (Noss and Hoyles 1996). Each student constructs personal intellectual structures that form his/her network of connections by utilizing what he/she chooses as appropriate and supportive from the pedagogical setting at the current time of learning. In that context, they focus on the flexibility of the computational learning environment and on the affordances that it provides to the learners so that they can gradually build and use such webbing structures within the environment. More recently, Weintrop and Wilensky (2014) described webbing as "a way to study the learning process as it emerges through the use of the affordances of the digital environment in concert."

Utilizing the construct of webbing, Weintrop and Wilensky (2014) designed a constructionist video game called "RoboBuilder." It is a program-to-play video game that "challenges players to design and implement strategies to make their on-screen robot defeat a series of progressively more challenging opponents in one-on-one battle" (Weintrop and Wilensky 2014). The environment integrates two distinct but connected components: a programming environment with block-based programming and an animated robot battleground. In their studies with RoboBuilder, Weintrop and Wilensky (2014) investigated how the connected features of the game environment contribute to a player's developing understanding of programming concepts.

Kynigos and Grizioti (2018) use the term "integrated constructionist designs" to describe enriched computational environments which didactically combine programming with other affordances. The affordances are carefully chosen to make complex scientific concepts accessible to students through multiple representations and at the same time support the construction of personal artifacts. An example of such design is ChoiCo (Choices with Consequences) (<http://etl.ppp.uoa.gr/choico>), an online authoring environment that allows the design and play of choice-

Computer-Based Learning, Computational Thinking, and Constructionist Approaches, Fig. 6 ChoiCo learning environment in Design Mode

driven simulation games that usually deal with complex socio-scientific issues. In ChoiCo games, the player revolves around different map-based settings and makes selections (these can be items, buildings, actions, etc.) that have specific consequences to a number of game parameters (i.e., Money, Health, Fun, etc.). The aim is to remain in the game by keeping the values of the parameters between specific red lines (limits). All the game elements can be designed or modified in the “Design Mode” of the environment (Fig. 6). ChoiCo integrates three affordances for the design of its games: (a) a map-based editor for constructing the game scene; (b) a modifiable database for specifying the consequences of the game items (choices); and (c) block-based programming for constructing the rules and the feedback of the game. The integration of these affordances provides access to complex scientific concepts such as randomness, patterns of behavior, event handling, data management, abstraction, etc. In addition, the genre of ChoiCo games (choice-driven simulations) combined with these three affordances allows for exploration, discussion, and expression of ideas related to socio-scientific issues with no profound solution. So far, there are a number of diverse games designed with ChoiCo for CBL purposes including games for environmental education, mathematics, computational thinking, ancient Greek, healthy diet, and ethics.

Computational Thinking and Constructionist CBL Approaches

Computational thinking refers to the mental process of understanding and solving problems through the efficient processing of information (Lee et al. 2011) and the construction of automated models, systems, and representations (Wing 2006; Lee et al. 2011; Grover and Pea 2013). For thinking computationally, one should develop a set of skills, strategies, and behaviors that come from computer science, but they can also be applied in other problem-solving contexts and situations. The set of skills that constitute computational thinking include among others decomposition, pattern recognition, generalization, abstraction, algorithm building, debugging and error detection, and information and data processing (Brennan and Resnick 2012; Grover and Pea 2013).

Despite the fact that computational thinking is considered one of the twenty-first-century competencies that students should develop, there is still no clear picture on how CBL should be designed in order to help students acquire and develop CT skills. Skills and abilities, in contrast to specific knowledge, are more difficult to be developed with traditional designs (i.e., instructionist or behaviorist designs) and to be assessed with closed exercises, quizzes, and tests. People usually acquire skills through experience and active

engagement in situations, and they should be able to apply and practice these skills in other contexts. For the development of CT, it is important to provide students with rich computational environments with low threshold and high ceiling that would allow them to transfer skills and knowledge in diverse situations (Grover and Pea 2013; Lee et al. 2011). The constructionism paradigm could inform such designs of educational environments in which students would develop CT skills by constructing and sharing personally meaningful artifacts with programming and other affordances.

However, in contrast to behaviorist approaches and guided quizzes, constructionist activities may require a great deal of time and effort from the students to familiarize with the environment, until they could actually apply, let alone develop, such skills. One popular approach that is used to overcome this problem is to provide students with scaffolds for building their artifacts. Students do not start from scratch to explore programming and create a new artifact, but they follow small steps of engagement. Many studies use the three-stage model of engagement “Use-Modify-Create” coined by Lee et al. (2011) for achieving a progressive engagement of young students in CT skills within rich computational environments. According to the model, children are gradually engaged with the affordances of the environment, transforming from users to creators and tackling with higher design challenges as their skills and knowledge increase (Lee et al. 2011). This model has been used for the design of CBL activities that focus on the development of students’ computational thinking, including game design, simulations (Lee et al. 2011), and game modding (Grizioti and Kynigos 2018).

A similar method to the above model is “remixing.” The Scratch community coined this approach as a way for enabling students’ progressive engagement with Scratch programming and with computational thinking skills. It refers to the process of finding ideas and code from existing Scratch projects and building upon them. This gives students the potential of creating much more complex artifacts than they could have created on their own (Brennan and Resnick

2012). Depending on the depth of remixing, it can require a high degree of sophistication and CT skills (Kafai et al. 2014). Recent studies on computational thinking have used constructionist digital environments, including Scratch, to investigate how students apply and develop CT skills while they construct, modify, or remix artifacts with them (Brennan and Resnick 2012; Grover 2017; Kynigos and Grizioti 2018; Werner et al. 2012).

ScratchMath is a large-scale research project that aimed to build mathematical knowledge and computational thinking skills through programming in Scratch during a 2-year intervention in a class context for students aged 9–11 years. In the first year, the intervention focused on computational thinking with an implicit mathematical component, while in the second year, it emphasized the exploration of key mathematical concepts using programming tools. According to the preliminary results of their study, their framework was “flexible enough for teachers to adapt to their own teaching style and experience as well as the needs of their pupils to communicate key computational and mathematical ideas in different ways whilst staying true to the goal of the learning activity” (Benton et al. 2017).

The Alice environment has also been used for studying the benefits of game design in the context of computational thinking development. One example is the iGame after-school in which students programmed their own digital games with Alice 2.2 and Storytelling Alice (Werner et al. 2012). The researchers studied students’ performance in the “Fairy Assessment,” an Alice program designed to analyze two CT skills: algorithmic thinking and effective use of abstraction and modelling. The assessment included three tasks with Alice, and it was designed according to the model “Use-Modify-Create” described before. Their results showed that students had increased motivation in programming after the program, but their performances between the tasks varied. The majority of the students had better performance in the task related to comprehension and less to that related to design. Another interesting finding is the increased CT

performance and scores of students who worked using pair programming in comparison to those who programmed alone.

Grizioti and Kynigos (2018) investigated how students apply and develop computational thinking skills when they progressively modified a simulation game. They designed a game modding activity in the CBL environment “ChoiCo” according to the model “Use-Modify-Create.” In the study, middle-school students, divided into groups of two, first played a “half-baked” game, then they improved it by fixing its bugs, and finally they created their own version of the game (mod) which they also shared with their classroom. Their study showed that students used the skills of pattern recognition, algorithmic building, and abstraction for recognizing and modifying the rules, items, and behaviors of the initial game. They also found an increasing complexity in the patterns and rules that students implemented from the beginning to the end of the activity.

Finally, there are a number of resources available for teachers and researchers, which describe methods for developing and evaluating CT with digital technologies in the classroom. For instance, a team from Harvard University in collaboration with Mitchel Resnick created a website where they provide examples, assessment methods, and support on using Scratch in the classroom, especially for the development of CT (<http://scratched.gse.harvard.edu/ct/>). In addition, Brennan and Resnick (2012) developed a computational thinking framework that emerged from their studies with Scratch and describes computational concepts, practices, and perspectives as well as assessment methods to evaluate them.

Challenges and the Near Future of CBL

For over two decades, constructionist epistemology has held a central role in computer-based learning. Especially now, with digital technologies and programming becoming an integral part of a new kind of computational literacy, there is a need for CBL designs that will promote creativity,

communication, and construction. The level of interactivity as well as the high freedom in construction and self-expression of constructionist CBLEs can make constructionism a strong pedagogical framework for the design of new CBL approaches that aim to cultivate twenty-first century skills including computational thinking and deeper learning. However, there are still some challenges that constructionist CBL environments should overcome.

Adaptability is an important element of CBL and involves the personalization of the learning process and the provision of feedback according to the needs of the learner. One question is how we can individualize a constructionist activity without restricting its open and exploratory character. How can we design a constructionist environment that would provide appropriate feedback to the learner without being strictly guided?

The design of CBLEs in which students would practice and cultivate computational thinking and other twenty-first century skills is also a challenge for the future of computer-based learning. There have been some first steps in designing constructionist environments and applying them in classroom contexts in order to support students to acquire such skills, like the examples we described in the previous section. However, there is still a need for assessment methods, curriculum designs, resources, and pedagogical frameworks for computational thinking to be developed.

The affordances of a CBLE can play an important role in learners’ engagement with the environment and in the knowledge and skills they would construct through this interaction. The challenge in this context is what kind of affordances should be integrated into a learning environment and how they should be combined together in order to support the generation of meaning and the construction of knowledge. For instance, should we focus more on block-based and visual programming or should we emphasize finding new ways to integrate textual programming with other affordances? This is an ongoing challenge, since each new affordance providing the potential for expressivity poses a need to study

the ways in which it may be put to use (Kynigos and Grizioti 2018).

Finally, scalability is always a challenge for constructionist approaches as there are still significant issues when it comes to their implementation in the school context. The implementation of such designs in the classroom usually requires time and effort from the teachers in order adapt their teaching. So, how can we smoothly integrate constructionist designs in a large number of schools, i.e., on a national scale? One approach that recently achieved a good level of scalability regarding both the number of schools and the duration in school years was the ScratchMath project described before. Another was the approach of micro-experiments, focused questions in constructionist environments that led to investigations, which are integrated into a digital portal accessed by hundreds of schools (Kynigos and Grizioti 2018). Similar approaches may open the way for constructionist CBL to be applied at larger scale.

Conclusion

Computer-based learning (CBL) has been used for almost 50 years in schools as a method to support the process of learning. CBL and the pedagogical frameworks that underpin its designs have evolved through time according to the technological advances of each era. The initial behaviorist and computer-centered approach of drill-and-practice technology was succeeded by exploratory systems and simulations that focused on discovery learning and by programmable, constructionist environments that emphasized the socio-constructionist perception of learning. According to different studies, computer-based learning can, in some cases, have positive effects on students' understanding and meaning generation in several domains. However, there are a number of challenges and factors that should be taken into consideration with respect to the pedagogical design of both the digital learning environment and the activities of CBL, in order to meet the needs of the twenty-first-century students.

Introduction

Various terms and concepts are used to describe how computers and technology generally are employed in schools and how they support

the training of teachers. Since its inception, educational computing and its associated terms have been shaped by both the technology itself as well as by prevailing teaching and learning paradigms and their associated psychological and pedagogical underpinnings. In its 60-year history, educational computing has evolved through three key phases, each lasting approximately 20 years. This evolution has not occurred in isolation, but rather has been a complex continuum involving a confluence of concurrent developments in technology, psychology, and pedagogy.

The first phase which ran from the early 1960s to the early 1980s ushered in the era of the teaching machine, where the computer was seen primarily as a surrogate or replacement teacher. Terms such as “Programmed Instruction,” “Intelligent Tutoring Systems,” and “CBT/CAI” (computer-based training/computer-assisted instruction) were invariably used to describe this new educational development where content was delivered to students in byte-sized chunks, followed by knowledge tests delivered by large expensive mainframe computers. However, the effectiveness of such systems were limited due to: costs which put them beyond the reach of most schools; technical constraints in terms of computer memory capacity; computational speed; portability; and, most important of all, the didactic nature of the programs themselves. In the context of the times, this didacticism is understandable given that teaching was primarily seen as an instructional or transmission-like activity based on behavioral psychology theory as popularized by B.F. Skinner (1904–1990).

The second phase, which was inspired by the invention of the microprocessor, commenced in the early 1980s. During this period, new developments in hardware and software technologies ushered in the era of the personal computer (PC) or desktop computer. As PCs became much more affordable, much smaller and more powerful, schools gradually began to purchase multiple devices placing them mainly in dedicated computer rooms for use by individual classes using a timetabled system. The lexicon of terms associated with this era such as “drill and practice,” “computer-based learning,” “multimedia

learning,” “interactive learning,” “computer supported cooperative learning” (CSCL), “micro worlds,” “hypermedia,” etc. gives an insight into the PCs evolving technical capabilities as well as the emergence of more modern learning theories and methods inspired by newer developments in psychology. While initially new courseware developed and delivered using CD-ROMs (Computer Disks Read Only Memory) on personal computers followed a similar instructional or “drill and practice” format to that of its mainframe predecessor, innovative practitioners and educational researchers inspired by cognitive and developmental psychology as well as constructivist learning theory began to push out the boundaries of educational computer use. In particular, the notion of a computer as a tool to learn with, rather than as a tool to learn from, gained prominence in research discourse; for policy makers and innovative practitioners, this meant that “the way the computer ought to be used in schools changed from a traditional understanding of technology-as-teacher to technology-as-a-partner in the learning process” (Jonassen et al. 1999).

The third and current phase, which began in the early years of the new millennium, was inspired by the invention of the internet, the World Wide Web and web browser technology in the mid-1990s. The communications and information revolution that the internet instigated greatly expanded the role and possibilities for school computing. It was now possible to provide online access to learning resources anywhere, anytime and utilize the web’s communications capabilities to support cooperative and collaborative learning as well as student dialogue, interaction, classroom exchange, and expert mentoring. A plethora of new terms emerged to capture technology’s enhanced educational possibilities such as “e-learning,” “online learning,” “virtual learning environments” (VLE), “blended learning,” “learning 2.0,” “mobile learning” (M-Learning), and “MOOCS” (massive open online courses), among others. In particular, the web’s communications’ features appeared to better accommodate the more social and cultural aspects of human development and learning advocated by psychologists such as Lev Vygotsky

(1986) and Jerome Bruner (1986). This led to a move away from the more structured and individualistic approaches to learning popularized by drill and practice software to utilizing more web-based communication technologies such as wikis, blogs, social media, conferencing tools, and mobile devices, which when appropriately deployed, had the potential to create richer, more reflective, and more active and authentic learning environments.

During this period, the devices used to facilitate learning changed, with desktops replaced by laptops, which in turn were replaced by smaller and more mobile devices such as chrome books, tablets, iPods, and even students' own mobile telephones in schools favoring a BYOD (bring your own device) system. This period also witnessed the introduction of Interactive Whiteboards (IWB), particularly in primary schools. These large interactive screens with instant access to the World Wide Web and other learning materials and resources replaced traditional chalkboards, whiteboards, and overhead projectors in classrooms. In many schools, the introduction of IWB technology and mobile learning devices, particularly where both technologies were utilized, meant the dedicated computer room as the main source of computing access declined, as varied Internet connected devices could now be deployed in classrooms and utilized throughout the school.

Given the ever-changing nature of school computing, devices, and associated methodologies, it can be difficult to define exactly what is meant by computer-based training (CBT). Traditionally the term was associated with use of computers to deliver training and teaching in the form of expertly designed courseware and tests without the physical presence of a human teacher or trainer during learning or testing. However, as technology evolved, alongside an increased understanding of the pedagogical limitations of using computers as surrogate teachers, especially in formal education, CBT became more of a catch-all phrase to describe the use of computers in education. Therefore, for the purpose of clarity in this entry, computer-based training is understood as a broad-based term that

encompasses any use of a computer for the purpose of assisting training, teaching, or learning in schools including the training of teachers.

Despite many exciting developments in educational technology and computers since the 1960s, and the increased, often (near) ubiquitous availability of devices, school computing has not had the impact expected of it, with ICT adoption and integration consistently falling short of expectations. From Cuban (1993) to Selwyn (2010a), numerous researchers worldwide have noted that the realities of computer use in schools fall short of the rhetoric, effectively meaning that despite the uptake of technology in education, ICT has not had a transformative effect on teaching and learning (Ala-Mutka et al. 2008) and has failed to achieve its full potential (Kampylis et al. 2012). While many research studies have pointed to individual factors such as poor infrastructure, inadequate teacher CPD (continuous professional development), first and second order barriers, technocentrism, policy deficits, and poor curriculum fit as the sources of the problem, others have adopted a more holistic approach by utilizing a sociocultural theoretical lens to focus on the wider context of schools as organizations and the interaction between technology, teachers, and school culture. Within social-cultural theory, culture is seen as a dynamic interaction between the individual and organizational environmental contexts (Rogoff 1995). Therefore, in the study of this interaction, socioculturalists take into account how cultural, institutional, individual, and social factors influence human behavior, and in the process unveil how deep, often subconscious, sociocultural practices, such as beliefs, values, norms, customs, and attitudes, affect how people think and act. In this respect, it can be argued that a full understanding of the integration and adoption of technology in schools must include the effects of social and cultural forces operating at an organizational and societal level.

To illustrate how this plays out in practice, the remainder of this entry will present the case of a multi-site educational technology project on Interactive Whiteboards (IWB) that took place over a 2-year period in Ireland utilizing a sociocultural perspective to analyze the findings.

IWB Project Background and Context

The IWB pilot project commenced in the second decade of the new millennium as part of an EU (European Union) project designed to facilitate the transfer of “good practice” in the delivery of IWB training in Ireland. Its core aim was to support the continuous professional development (CPD) of teachers and trainers working in the vocational educational and training sector (VET) on the use of Interactive Whiteboards. To achieve this aim, Irish VET teachers and tutors were provided with a comprehensive training program involving seminars and workshops as well as a range of print-based CPD materials and a series of online instructional videos covering all aspects of IWB use catering for both novice and advanced users. An online Community of Practice (COP) website was also provided.

A total of seven Irish VET schools (officially referred to as VET centers) participated in the pilot. All were involved in teaching adults, at-risk youth, and second chance education learners (i.e., both young and older adults who, having left school early without obtaining formal qualifications, had now returned back to education). Therefore, the aggregate age span of their students ranged from late teens to early 60s. While overall responsibility for the project’s implementation in Ireland lay with the Regional Coordinating School Authority, a project champion working in each school center was responsible for the day-to-day implementation of the project at local school level. Each project champion was a school-based teacher who was selected to become a champion following an open recruitment process. All were chosen based on their ICT competency (not necessarily with IWBs, although some had this experience), their ability to act as role models for others in using technology, as well as interest in and enthusiasm for the project. Notably, most project champions were younger teachers with less than 10 years’ teaching experience. The project champions were the first group of teachers to benefit from training on IWBs devised by the EU project partners before going on to assist as trainers on

courses, workshops, and seminars organized for participating schools.

Research on the IWB project took place over a 3-month period towards the end of the project’s final year. The research was conducted using a series of case studies involving semi-structured interviews as the main data collection tool supplemented by artefactual analysis of the community of practice and other project materials. More than half of the schools participated in the research. Interviewees comprised three groups involving: (a) Teachers/Tutors; (b) Center Coordinators (i.e., School Principals); and (c) Project Champions. For the most part, Teachers/Tutors participated in Focus Group Interviews, consisting of 3–5 participants, while School Principals and Project Champions were individually interviewed. A total of 32 participants ($n = 32$) took part. While the research aimed to capture a number of project outcomes, the most important findings to emerge from an analysis of the research data, and the most relevant from this entry’s perspective, were related to:

- Teachers’ use and integration of IWBs
- The role of the Project Champions
- The effectiveness of the online Community of Practice concept and platform for supporting collaboration and sharing of resources and expertise in relation to IWB CPD

Teachers’ Use and Integration of IWBs

The widespread introduction of IWB technology in schools “opened up the possibility of integrating technology more fully into teaching and learning in every curriculum subject” (Moss and Jewitt 2010). Since their adoption by schools from the early 2000s onwards, IWBs have become a permanent fixture in many classrooms. Research evidence from many countries, but particularly the United Kingdom (UK), most of which was gathered between 2000 and 2010, revealed that teachers used and integrated the devices to support classroom learning. Once initial learning curve hurdles were overcome, teachers for the

most part embraced the technology, utilizing its many features such as interactivity, enhanced presentation capabilities, drawing and annotation tools such as infinite cloner, and drag, drop, and reveal among others. However, the technology was not without its detractors, with some researchers cautioning that teacher enthusiasm for IWBs was due in no small way to the manner in which it fitted into traditional classroom teaching practices (Somekh et al. 2007; Dudeney 2006), thereby reinforcing didacticism and whole class teaching (Gray et al. 2007), rather than transforming teaching methodologies and existing ways of working (Moss et al. 2007; Coghill 2002). In this respect, the device could be viewed largely as a teaching tool more suited to teacher use rather than a learning tool for use by students. Nonetheless, numerous studies from the first decade of IWB use in schools as well as more recent studies (Passey 2016) indicated that the device, especially when used as a form of “digital hub,” (Moss et al. 2007) helped teachers to integrate and make better use of ICT in classrooms.

A key objective of this research study was to capture the extent to which and in what way VET teachers were using IWBs to support teaching and learning. Having previously conducted research on the first IWB project in Irish schools nearly a decade earlier, which illustrated how IWBs had positively influenced ICT integration (Judge 2010), a similar outcome was expected here. This turned out not to be the case with 14 (66%) of 21 class teachers interviewed revealing that they had not used the IWB since participating in training. Furthermore, of the other seven teachers who had used the IWB, only three described themselves as “regular IWB users” with the remaining four using the term “occasional IWB users” to describe their level of use.

This relatively low number of project participants claiming to use IWBs regularly was clearly unexpected and disappointing. Fortunately, the research interview process afforded space and time to explore the issue more fully and in greater depth with participants. A subsequent systematic analysis of the research interview data revealed that a number of factors were responsible for

participants’ nonengagement, the most important of which were:

- Problems with initial training
- Time and timing issues
- Staff contractual arrangements and insufficient resources

Initial Training

Research feedback from participants indicated that the majority of teachers were disappointed with the initial training courses and workshops as they felt they had neither met their needs nor delivered on what was promised. Most teachers believed that they were too theoretical, with no time, or very little time, allocated for practice. It was felt that too much course time was devoted to explaining the academic rationale behind IWB usage leading to an over-emphasis on “show and tell” rather than “learning by doing.” A number of teachers were also quite suspicious about the motives behind the training course, believing that they were largely a promotional exercise by SmartBoard, the IWB board manufacturers themselves, to promote their product. Although this was clearly not the case, as the manufacturers were not involved in any way, it is interesting that this is the impression that came across in some quarters and it was clearly off-putting for those teachers. In the aftermath of the initial training, teachers felt that they neither had the skill set nor the competency to commence using the IWB in their classrooms. As one Project Champion articulated:

I think here the initial training went reasonably well but my feeling was that some people were quite negative about the lecture style format. So I feel in terms of both presentations there was a tendency to be too academic about it and that really didn't go down well, even with people who had a strong background in educational theory. They felt they were being talked down to and they just felt alienated by it.

In a similar vein, another teacher commented:

I signed up for it originally because I had never used whiteboards before and my whole idea was that through the training I will get more hands on and get experience on how to work it so that I might

be able to use it with my class. But I ended up dropping out of it because it was too theory based, more go off and do your homework type thing. Because I wasn't getting the opportunity to do the hands on work, I felt it wasn't hitting what I needed, so I felt this is not what I signed up for; this is all just paper exercises, no hands on, and none of us needed any more paperwork.

Unfortunately, the disappointment in the content and direction of initial training had serious implications for the project's development, as the majority of teachers immediately lost interest in the project. As one Principal noted, *"while the majority of staff attended initial training only two staff members pursued it to the end which is a pretty high rate of attrition."* This is despite the fact that although the local Irish project team tried their best to rectify the initial training issues by designing and delivering a more practical hands-on bootcamp-style training workshop in the project's second year, teachers did not re-engage. For those who did attend, the boot camp model was very favorably received and strongly praised and endorsed by the teachers who participated:

The boot camp was great. I would have liked the boot camp to come first because it was more experiential learning and I think that even people who were new to the whiteboard would have got more of an opportunity in a fun kind of way to begin working with it.

In hindsight, it is clear to see that initial training which was fundamentally "top-down" in nature was not fit for purpose; instead, as Schmidt and Schimmack (2010) demonstrated in their research on IWB training for teachers in Germany, a "bottom-up" model involving teachers themselves in training design is the desired and far more effective approach. Furthermore, as other research has illustrated (Pearson et al. 2004; Somekh et al. 2007) continuous and on-going CPD, preferably conducted on site rather than a single training event usually conducted at the beginning of an innovation, is far more effective in promoting successful IWB use.

In fairness to the project leaders, while face-to-face training workshops and seminars represented the main vehicle through which teacher training was provided, additional materials to support ongoing CPD training such as training manuals,

instructional videos, and an online community of practice site were also provided. However, research feedback revealed that most teachers did not use or consult these resources over the course of the project. Lack of time and lack of interest were cited as the main reasons for not using these resources. The problematic issue of time and how it affected overall project engagement was singled out by most participants and this will be discussed in greater detail in the next section.

Time and Timing Issues

Time was one of the biggest impediments to IWB usage cited by virtually all interviewees. The time barriers appeared to have a number of dimensions which could be classified as "Bad timing," "Lack of time to practice" and "Lack of time to develop resources." This is not unusual. As Selwyn (2011) reminds us, "time is often highlighted as an overriding concern in studies of teachers' work." This is especially true when it comes to ICT, where teachers frequently identify lack of time as a barrier to ICT adoption, as noted by Judge (2007) in her ethnographic research study on the Wired for Learning Project in Ireland and earlier large-scale quantitative studies conducted in the United States of America (USA) by the Office of Technology Integration (1995) and Quality Education Data Inc. (1995, as cited in Su (2009).

There was a general consensus among all interviewees that the IWB Vet project timing was unfortunate, as it was introduced at a time when the entire VET curriculum was undergoing a major overhaul nationally. This meant that teachers were busy investing all their time and energy in developing and delivering new modules or revamping existing modules, which seriously impacted the amount of time they could devote to the project. This was a source of frustration to some teachers who could clearly see the potential benefits of using IWBs in class but felt they had to prioritize the development of teaching materials for the new curriculum above the IWB project. According to one Principal, this was perfectly understandable as *"teaching has to come first because that is what's valued"* whereas the IWB

project was seen as a temporary fad – “*something that would come in and go out again.*” The loaded nature of this comment should not go unnoticed, as it seems to suggest that Larry Cuban (1986, 1993) was right when he argued that technology has failed to affect schools due to dominant cultural beliefs that permeate both schools and society, which sees teaching as telling and knowledge as a subject matter to be taught by teachers via traditional materials such as books.

Many teachers reported that they did not use the IWB in the aftermath of training; due to the newness of the device, they felt they needed time to practice on it before feeling sufficiently confident to use it in front of the students. Although the software could be loaded onto their laptops for them to practice on in private, and many availed of this facility, teachers reported that experientially this was not the same as actually using the IWB itself. Therefore, despite having the opportunity to experiment with the software on their laptops away from the gaze of students, they still did not feel confident going into class and using the IWB in a live classroom situation.

In addition, many teachers argued that preparing resources was very time consuming, as research elsewhere has also found (Glover and Miller 2001; Lai 2010), and expressed disappointment about how much effort was required to produce even the smallest learning resource. This constraint was best summed up by one teacher who said that it had taken her 4–5 h to create a resource for a task which only took 90 s of class time for a student to complete. Given this ratio, teachers felt that the gap between the end product (resource output) and the level of investment required (teacher input) was too great. There appeared to be little appreciation for the fact that having created a digital resource it would be permanently available for use, re-use, and modification in years to come or that as teachers developed more expertise with IWB technology, resource creation time would also reduce.

The issue of time was further compounded by the fact that very few teachers had permanent access to an IWB in their classrooms. As only a small number of rooms in each center were

equipped with an IWB, teachers had to book these rooms in advance in order to practice using the technology or deliver an IWB-prepared lesson to students. This was a serious problem, which acted as a major impediment to usage post training. This is in line with research evidence from elsewhere (Pearson et al. 2004; Somekh et al. 2007), which argues that teachers are more likely to use and make best use of an IWB when they are permanently available in their classrooms, whereas, as Haldane (2008) points out, fragmented access to the technology negatively affects both teacher competence with and motivation to fully use and exploit the IWB’s capabilities to prepare and deliver lessons.

Staff Contractual Arrangements

A further complication with regard to time required for up-skilling related to the nature of employment in the VET sector, as many teachers are part-time workers, some working as infrequently as 3 h per week, unlike full-time staff who have a teaching allocation of 22 h per week. Part-time teachers are paid on the basis of student contact time only, which means that there is no real incentive to become involved in training or undertake further professional development. This means that involvement in professional development and training is largely dependent on the goodwill and intrinsic motivation of the individual teacher.

Some teachers expressed strong objections to participating in professional development activities for which there was no additional remuneration; some teachers, although expressing willingness to up-skill at their own “time expense,” found themselves unable to do so due to childcare and caring commitments for loved ones which were too difficult to reorganize. There were also significant out-of-pocket expense implications for covering childminders and professional carers for extra hours worked to cover their involvement in training.

This posed a problem for project champions particularly as they felt they could not expect hourly paid workers to get involved in IWB training when they were not being compensated for the extra time required to upskill. Even teachers who

had full-time teaching contracts experienced difficulties finding time to develop their IWB skills, especially when there was limited access to IWBs in their school or training center.

All of these factors encompassing initial training difficulties, time, and timing, as well as staff contractual hours, meant that the Project Champions located in each school faced an uphill battle when trying to encourage staff to use IWBs to support teaching and learning. The somewhat problematic and challenging nature of their role will be discussed more fully in the next section.

The Project Champions

From the outset, the project identified peer tutoring and the role of project champions in facilitating this as central to the project's modus operandi. It was envisaged that the project champions, located in each of the participating centers, would act as coaches and tutors to other teachers in the project. Furthermore, the project champions were seen as a conduit through which a community of practice focused on sharing knowledge and expertise in relation to IWB pedagogy and peer tutoring among teachers could emerge. In line with the philosophy underlying peer tutoring and collaborative best practice, it was deemed important that the champions should be seen by their peers as facilitators rather than as IWB experts.

It was envisaged that the role the Champions would play on site in their own training centers and schools would be most important for the success of the peer tutoring and community of practice model that lay at the heart of the IWB project. Feedback on their function was very positive, with both fellow teachers and school principals describing them as "enthusiastic," "supportive," "knowledgeable," "empathetic," "willing," and "available." The small number of teachers who availed of their services found their support and encouragement invaluable, particularly as it helped to bridge that confidence gap which often arises between training and actual implementation.

From the perspective of School Principals, the provision of one-on-one training and on-site

mentoring by the Champions was essential in terms of helping to maintain overall project momentum through "*handholding some of our teachers who are very needy*" and "*making sure we were kept up to date with the whole project.*" However, despite the high praise from their peers and principals, the Project Champions themselves were more circumspect about their role and achievements and most expressed disappointment at the level of commitment to the project from their colleagues. In reality, most Champions found that few teachers contacted them for help and support even though they did their best to continually remind colleagues of their availability through regular emailing and other means.

Although project buy-in was clearly an issue in some quarters, other factors such as logistical difficulties in terms of peoples' scheduled teaching hours also played a part in frustrating Champions' efforts to support teachers in the way they would have liked. Some champions taught in more than one school center so, therefore, they were not permanently available in one location; most Champions were teachers with significant teaching contracts and therefore were not always free and available, especially to teachers who only came into school to teach their contracted 3–4 h a week and were then gone. This was a source of frustration both for them and for those who needed their help.

Project Champions also expressed concerns about the level of IWB training that they themselves had received. When they applied for the roles, they had understood that they would receive a lot more training with IWB technology before being required to train others. The reality, however, was somewhat different, and consequently they found themselves only one step ahead of those they were expected to train. For most, this was an uncomfortable space, leading directly to the resignation of one Champion, who felt he could not really describe himself as a "Champion," because he did not know enough about the technology.

But, perhaps more importantly, the Champions' role was also constrained by their position and sphere of influence within their organizations. It was noticeable that most Champions

were much younger than many other participants interviewed. Furthermore, they found themselves in the unenviable position of being responsible for driving a project in their local school centers without having any real authority over whether people participated or not. In this respect, they operated at the whim of other people's good will, which was less than ideal situation, particularly when difficulties arose along the way, such as the initial dissatisfaction with the early training course, for example.

Fundamentally, this was largely an organizational management and leadership issue which could have been avoided if the School Principals had taken a more proactive approach to the project's development and the staff engagement challenges their Champions faced. Instead, School Principals tended to take a hands-off approach with one Principal saying: *"from my point of view it was great having the champion here because it meant the staff didn't have to come to me for help"* and another noting: *"it's not that our staff didn't buy into the project, they just didn't buy into the extra work that it involved."* Such comments tell their own story. As anyone ever involved in any school innovation initiative knows, every new project, particularly technology-related projects, requires extra work and commitment from staff, above and beyond normal work hours. Securing people's commitment to these extra work hours is fundamentally a management and leadership issue, which in terms of the implementation of the IWB project was not adequately addressed. Failure to do so left the Project Champions in a difficult position when it came to galvanizing those around them to devote extra time and energy to becoming IWB competent.

Obviously, every new project and every new role brings its own set of challenges. By and large, the Project Champions were passionate and pragmatic participants who were committed to the role they had undertaken and who dealt with the challenges encountered to the best of their ability. The overall sentiment from their involvement in the IWB project was that it was a positive experience for them personally, from which they learned a significant amount in terms of developing their

technical expertise in IWB technology and further developing their ICT pedagogical skills. Nonetheless, in terms of upskilling their colleagues in the use of IWB technology, and thereby affecting change in pedagogic practice, they were severely constrained by a number of factors, in particular their youthfulness and lack of any real authority in the system's "pecking order," compounded by an abdication of leadership by School Principals when it came to supporting them and the IWB project.

The Online Community of Practice

According to Wenger-Traynor (2015), communities of practice (COP) are "groups of people who share a concern or a passion for something they do and learn how to do it better as they interact regularly." Effective learning communities provide members with opportunities to build on the individual's and the group's knowledge, take risks without fear of failure, and develop expertise and experiences with many different activities. With the growth of web 2.0 technologies, teachers, like many professionals, are increasingly participating in online communities of practice, forum discussions, and other online activities to enhance their learning. According to Trust (2012), highly effective teachers learn through collaboration, professional development, and research into best practices.

Developing an online IWB Community of Practice was an important dimension of the project. It was envisaged that this resource would act as a vehicle to help teachers to develop and share materials and their learning experiences with IWBs as well as advancing their ICT skills through experiencing how social networking and communication tools could be used to support learning and reflection.

The project's online community of practice was built utilizing an existing eTuition COP hosted on a Ning-based platform which provided an online network for teaching and support staff working in the VET in Ireland and the UK. The underlying eTuition architecture contained a number of tools which supported teamwork and

community interaction, such as discussion forums, repositories for storing and exchanging content, blogs that could be updated on a daily basis, notice boards for communications, and personal profile areas containing photographs, contact information, and other relevant details of community members.

Unfortunately, teachers did not engage with the eTuition site. Hardly anyone interviewed had uploaded lesson plans to the site other than those which had been completed during training workshops. A check of the eTuition site itself confirmed this situation. Discussions with interviewees uncovered a number of reasons for teachers' nonengagement in the online COP, which on further analysis could be classified as technical issues, confidence issues, and work practice issues.

On a technical level, people found the eTuition site difficult to navigate and use. The site itself was viewed as "clunky," "cumbersome," "confusing," and "not very user-friendly." This criticism was universal across the board, from the most "tech-savvy" teachers and Project Champions to the most techno-phobic participants. Many teachers also expressed concern about the resources they created being visibly available to a wider audience. In part, this was due to a lack of confidence in the quality of the lessons they produced with some saying they were "*embarrassed about the quality of their own lesson materials*" believing they were "*not good enough*" or professionally polished enough to publicly share with others. For other teachers, the reluctance to share materials was tied up in fears about being judged by their peers and a belief that the time they invested in developing resources would not necessarily be reciprocated by others.

Undoubtedly, a large part of the reason teachers did not create lesson plans as requested can be explained by traditional work practice mores. As teachers are not obliged to work beyond their contracted hours, very few were willing to put in the extra personal time which preparing IWB lessons and coming to grips with the eTuition site involved. This was particularly true in the context of the prevailing political and

economic climate at that time, where, as a result of the collapse of the Irish Celtic tiger in the aftermath of the global recession of the late noughties, Ireland required an IMF (International Monetary Fund) bailout to keep its economy afloat.

Under this new regime, teachers had their salaries cut significantly, were forced to make higher pension contributions and were also required to work an extra 33 h per school year without any additional remuneration, under what was officially known as the Croagh (pronounced Croke) Park Agreement negotiated between the Government and Public Service Trade Unions. Effectively amounting to an extra 2 h per week during school term time, the agreement stipulated that the 33 h had to take place outside of normal school teaching time in order to avoid any erosion of class contact time. Colloquially, the extra 2 h became known as the "Croagh Park Hours." Across all levels of the education system, and not just in the VET sector, a lot of teacher goodwill and the voluntary ethos that had traditionally permeated the Irish education system was eroded as a result of these enforced changes. Unsurprisingly, when teachers saw how much their take-home pay was reduced, they resented putting in those extra hours, small as they may seem to an outside observer. Invariably this resentment affected project engagement. There are parallels here with findings from a later study on the adoption of iPads in a Portuguese school where years of austerity and cutbacks had also adversely affected some teachers' motivation and goodwill (Judge 2017).

The adherence to traditional work practices and ways of doing things was also evident in people's reluctance to engage with each other in the online space. Many teachers said that they could not see the point of online communications and the benefit for their professional practice. This is understandable when you consider that very few participants had ever undertaken online training before, participated in a community of practice or even collaborated with colleagues in their schools to share resources or develop teaching materials in the offline world, never mind the online environment. As one Principal observed, "*there's no point in having something online when*

they don't meet face to face anyway to discuss common areas" and another noting *"we already have a community of practice – it's called a staffroom where we all meet each other daily and interact."* Furthermore, teachers themselves admitted to preferring face-to-face communications and attending training delivered in a physical setting rather than in a virtual space. All these findings point to a culture, a *modus operandi*, and a mind-set among both principals and teachers that was very traditional indeed.

Conclusion and Final Comments

This case of an Irish IWB project provides a window in which to view what Selwyn (2010b) calls "the messy realities of digital use in schools" which in this instance manifested itself largely as a form of nonuse. As he also argues, the technologically deterministic orientation of much academic scholarship on ICT in education has done a disservice to the process of ICT adoption and integration in schools by ignoring the socially shaped contextual nature of school-based technology in which economic, political, organizational, and cultural factors all have a part to play. The multitude of factors that inhibited the adoption of IWB technology in these VET schools illustrate clearly why a sociocultural perspective can help us better understand the complexity of ICT adoption in schools. No single isolating factor was to blame for teachers' lack of engagement. The story here was much more intricate, much more complex, and much more nuanced when examined using a sociocultural framework to unpick the various layers.

Firstly, looking at the macro context, it is clear that the wider international/national political and economic climate which no school authority had any control over played a part, as teacher resentment over altered pay and conditions and mandatory unpaid hours rose to the surface when asked to invest more personal time in technology upskilling. In venting their frustration about the time required to master IWB technology and the accompanying Community of Practice, their anger was not directed at the project per se, but

more at the political and economic situation they found themselves in, which were completely external to the project. Consequently, the project became a vehicle, which allowed them to publicly articulate their anger about their altered circumstances, probably for the first time, in any meaningful way by downing tools through little or no engagement. As a result, the project, and with it the IWB technology and the Community of Practice it sought to introduce, became a victim of the more global macro context affecting all areas of Irish life, including schools and teachers, at that point in time.

Secondly, at a meso or system level, issues involving the introduction of a new national curriculum, school leadership and institutional arrangements such as inconvenient scheduling of activities and lack of resources were also influential. In terms of the new curriculum, teachers felt they were already stretched and overworked trying to meet its demands. With competing demands from two new initiatives, they viewed the design and implementation of new curriculum modules rather than upskilling on IWBs as their key priority. Teachers are by nature pragmatic people and no different from other professionals in that they know that what gets measured gets done. There were no real sanctions for the individual teacher or individual school if they did not adopt IWBs or did not engage in the Community of Practice. In contrast, no teacher wants to incur the wrath of his or her Principal or District School Inspector by not completing module revisions and redesigns on time for curriculum reform mandated at a national level. In this respect, there was a failure at central level in the VET system to anticipate that introducing a new technology to schools at a time when curriculum reform was also being implemented might prove problematic.

There was also a failure of school leadership. The successful implementation of any new school initiative including technology depends on leadership. By its very nature, school innovation involves change and as an initiator or implementer of change, the principal plays a crucial role (Sarason 1996). It is the principal who sets the tone when it comes to promoting new projects and encouraging teachers to integrate ICT into

teaching and learning, as well as building the organizational capacity for change. Both the attitude and the behavior of principals are clearly noted by staff and have a significant influence on how staff think, behave and act. Principals needed to buy into the project; rather, they had adopted a hands-off approach in leaving so much of the project's implementation to the Project Champions, most of whom were too young and too inexperienced to handle the organizational change implications which ICT projects like this one inevitably involve. It is no surprise that leadership support, or lack thereof, can make or break the adoption of innovations involving new technology, as it is principals in their capacity as school leaders who ultimately influence how teachers and schools embrace innovation and respond to change.

Finally, at the individual and micro level, some of the most important issues that emerged had strong cultural underpinnings. Although hard to identify as it is largely implicit (Schein 1992), sociologists believe that culture is the context in which things happen in society, institutions, and organizations. The concept of culture which Boas (1930) defined as "the social habits of a community" and Smith and Bond (1998) as "systems of shared meaning" or more simply by Deal and Kennedy (1983) as "the way we do things around here" is ultimately intertwined with organizational norms and values which influence and shape how groups and individuals think. That is why Sarason (1990) suggests that school culture must be taken into account when trying to gain a better understanding of the school organizational context in order to understand the dynamics of school systems and how its multiple contexts impede the success or failure of innovative CBT endeavors. As Cuban (1984) reminds us, "the cultures of teaching that have developed within the occupation tilt towards stability in classroom practices." This means that teachers and schools are fundamentally cautious, prefer stability, and are skeptical when it comes to implementing or adopting change presented by new methods or new CBT technologies.

In particular, the difficulties associated with the e-Tuition Community of Practice boil down essentially to the problem of culture and the interaction between dominant organizational cultures and change when new technologies are introduced. It has long been acknowledged that the predominant school culture tends to be individualistic, with teachers working in isolation. The structure of the typical school day affords little opportunity for teachers to work together or to exchange ideas on a sustained basis when compared to other professions. This problem is accentuated in the Irish VET sector due primarily to the number of teachers working part-time where time physically spent in the organization is very much confined to the classroom, affording few opportunities even for small things like "water cooler moments or conversations." Therefore, when new technologies such as IWBs or the eTuition site come along with the potential to develop new professional practices, they challenge the way teachers traditionally work and how they communicate, interact, and share with each other, thereby bringing to the fore many deeply held beliefs about what teachers do and how the school and teaching culture operates. Because there was no tradition of VET teachers working together both within and across schools in the offline space, expecting them to work together in a virtual environment was always going to be challenging.

In summary then, based on the findings and discussions in this entry in relation to the deployment of CBT in schools, a number of lessons have been learned about the factors affecting its adoption, particularly when it comes to teacher CPD, which are best summed up in Table 1.

To conclude, the issues and roadblocks reveal the extent to which the introduction and adoption of new technology for CBT is fraught with challenges involving not just technological competence but also professional and organizational cultures, involving how people and the school system react to changes implicit in the adoption of new technology. When viewed through a sociocultural lens, it is easier to see how the biggest challenge facing ICT adoption and CBT in

Computer-Based Training and School ICT Adoption, A Sociocultural Perspective, Table 1 Key factors, constraints, and lessons for CBT adoption

Factor	Constraints	Lessons learned
Initial Training	Overly didactic and theoretical	Replace “Show and Tell” with hands-on and experiential learning.
Insufficient time	Lack of time to practice and develop resources	Allow sufficient time for teachers to practice and develop resources in order to confidently integrate CBT in classrooms.
Bad timing	Tension between project demands and national curriculum reform agenda	Timing is important, so where possible, avoid introducing new technology projects in schools when teachers are already working on other innovations, especially those with nationally mandated deadlines.
Staff contracts	Part-time staff are paid for teaching contact time only	Build training time into part-time teacher contracts so that they can up-skill on CBT as needed, particularly when it comes to new initiatives.
Project champions	Age level/experience and lack of leadership support	Recruit senior staff as Project Champions who have sufficient experience and gravitas to drive CBT projects; ensure School Principals are fully supportive of any new technology innovation.
Online community of practice (COP)	Technical difficulties and traditional work practices	Remove technical obstacles to teacher engagement with COPs by using platforms built on up-to-date technologies that are user-friendly and intuitive; recognize that traditional work practices present many practical and conceptual constraints to teachers’ engagement with a COP.
Sociocultural	Global, national, institutional, local, professional and individual contexts	Adopting a sociocultural perspective to the process of CBT adoption in schools reveals how a complexity of factors operating at macro, meso, and micro levels influence how schools and teachers respond and react to innovation and change.

schools is not so much about acquiring new technical skill-sets; rather, it is more about shifting mind-sets in terms of thinking and operating differently as teachers and as organizations, in the face of new technologies that offer a different and new way of working, thinking, and learning.

Introduction

This entry deals with the intersection of the use of computers (mainly in state or public rather than private or independent schools), dating from the late 1970s to the present day, with educational improvement (also in schools). It draws on experience in the school systems in the United Kingdom (UK), with examples from Northern Ireland (NI) in particular, although aspects refer to educational technology contexts across Europe.

As has been recognized for some 20 years and, as will be argued in this entry, uses of digital information and communication technologies (ICT) are deeply and irremovably embedded in a multifactorial way in many aspects of the life and work of schools, all of which contribute collectively to school improvement (NFER 2000; OECD/CERI 2001). Computer technology applications which are focused on one aspect of learning and teaching, leadership and management, or professional development may well make a valuable contribution to improvement, but the premise of this entry is that it is the organized, holistic, whole-school approach which makes the difference to school improvement.

Overview

This entry summarizes the evolution of computers and their place in schools over the past 40 years and outlines how educational applications and content developed as the technology advanced. These developments are then related to improvement in the context of pedagogy and the school curriculum, drawing on the UK as a context.

The entry then deals briefly with how the UK government responded to their recognition of the link between computer use and educational improvement and goes on to explain how, as a result, the growing diversity of educational technology is now embedded across the life and work of schools.

In dealing with the role of technology in teaching, assessment, and learning, the entry sets out:

- How the teaching and assessment of related skills evolved from ICT user (“e-skills”) to higher-order thinking skills and to a

progressive framework for digital skills, using Northern Ireland as an example.

- How technology can be embedded in ways that can raise standards, especially through the pedagogic quality of educational applications.

The entry ends with shorter sections on the role of computers in supporting improvement in the management and leadership of the school and in how digital and online technologies are used as a professional tool by teachers as practitioners to improve their practices.

Educational improvement is a theme that flows through all sections.

The Evolution of Computers and Their Place in Schools

The variety of different ways in which computers are used in schools today derives from the evolutionary stages of development in hardware and software over the past 40 years. During the 1970s, only a few UK schools used mainframe computers in teaching computer science. A national government programme, the National Development Programme for Computer Assisted Learning from 1973 to 1977 (McDonald 1977), developed projects in the use of mainframe computers focused on their use for learning in subjects other than computer science. It supported some 35 projects, mainly in tertiary education, but seven of which were in school subjects where content resources and algorithms to help learners manage their learning through computer-based tests were developed.

The first microcomputers appeared in schools in the UK in the late 1970s. The Commodore PET microcomputer had a small, green-text display screen and an audio cassette tape for data storage. The programming environment and programs had to be loaded every time the machine was switched on, and any new program saved to cassette before it was switched off. The most that could be done from an educational point of view was to write code, in BASIC (a simple programming language) or in PILOT (an authoring language)

for elementary skills drills and multiple-choice quizzes for a single user at any one time, representing a very limited model of pedagogy (teaching and learning). Users could also develop early examples of control technology, by programming simple robotic projects (interfaces easily addressable with machine code) that controlled, for example, model railways and model toys and lights.

In the early 1980s, the Department of Trade and Industry, following a ministerial initiative from (now) Sir Kenneth Baker, introduced a “Microcomputer in School” scheme, to provide direct access to at least one microcomputer in each school by the end of 1982, with the dual intention of supporting the British microcomputer industry (Acorn Computers, Research Machines and Sinclair) and supporting teaching and learning, both *about* computers and *with* computers. During the 1990s, as the number of computers in a school grew, networked but stand-alone computer rooms were constructed, which allowed the pedagogy to evolve from demonstration of a software package by the teacher to a group of pupils clustered around a monitor to whole-class computer-based tasks and activities, often using drill-and-practice programs, typically to practice simple skills or to run an instructional package.

More recently, in the late 1990s onwards, as the Internet spread in availability, initially through school connectivity to university-based networks such as JANET (the Joint Academic Network), school computer rooms were connected to the Internet. Later, in a planned and systematic way across the UK, Regional Broadband Consortia (10 consortia in England and one each in Wales, Scotland, and Northern Ireland) were promoted as a UK government “National Grid for Learning” initiative (NEN 2018). Schools invested in wired network infrastructure around the whole building allowing, at the very least, a computer on each teacher’s desk (largely for simple administrative recording tasks such as attendance) and some clusters of computers for specific learning purposes in, for example, technology and art rooms. For a period of time, from around the early 2000s, interactive “whiteboards” installed at the front of a classroom were popular with teachers because

they were in the “teacher’s space” and supported readily a didactic, show-and-tell, whole-class style of teaching. However, the interactivity which they afforded was rarely exploited by teachers (despite some very imaginative interactive educational software) who tended to use the device as little more than an expensive data projector.

Eventually, by the early 2000s, digital computer devices became, generationally, smaller and more mobile. With the introduction of wireless networks in schools and the evolution of web-based software environments, laptops and handheld digital devices became, initially, a supplement to computer rooms and then pervasively, personally used and individually owned tablets and smartphones supporting an “always-on” Internet connectivity.

The Development of Educational Content

As computer technology advanced over the decades, with increasingly more powerful and faster microprocessors, it enabled software applications which moved on from simple skills training programs, through simulation packages with increasing sophistication, through to productivity and design packages which put the control of design and development of applications into the hands of the user, with greater ease of use, more accessibility, and less and less specialist user training needed.

As processing power, display unit capability, and storage devices improved, graphics were used to illustrate and animate processes which could help to illustrate and animate for a learner how systems or processes (mathematical, physical, chemical, biological, environmental, technological, and so on) worked – initially like an interactive display which the teacher could use to “show and tell.”

The quality of rendered graphics improved, becoming less diagrammatic and more realistically “lifelike,” to the point today where computer-generated images are often undisguisable from a video or filmic presentation. At the same time, the

increase in the number of computers in each school, and especially on networks, opened up the potential for learners to be in control of and explore an educational package (at least where the teacher made the pedagogic decision to plan the learning activity in that way) – affording a potential step change improvement in pedagogy.

However, not all innovations led to an improvement in outcomes. In the 1990s, Integrated Learning Systems (ILS) were popular in the United States of America (USA) and were supported by some large educational corporations. The UK government, seeking a solution for literacy and numeracy challenges, supported an evaluation of suites of networked packages that provided individual tuition in mathematical and language skills. The evaluation revealed that teachers varied in their appreciation of how to build their use of ILS into their teaching and that, while careful use could improve the test score of some learners within the ILS package itself, it did not often lead to all-round skills improvement in literacy and numeracy (BECTA 1998).

As educational programs became much more sophisticated, they required a much higher level of programming skills, leading to educational programs being written by computer programmers, with sometimes very little understanding of teaching and learning. As the market for educational software grew, there was an explosion, initially in the UK, of educational companies being set up and run by teachers, producing very sophisticated educational packages, especially for the larger primary school markets.

The greater ease of online communication through Internet-connected computers also made its contribution, enabling pupils across the world to communicate and learn together through some remarkable projects (Austin and Anderson 2007; Austin and Hunter 2013). However, the impact has been much less on education in schools compared to that at the tertiary level, both of which pale into insignificance compared with the uptake of online computer gaming; but then, online gaming has grown as a new enterprise, unlike education systems which work within an existing set of institutional frameworks which are often, by their

very nature, conservative, resilient to innovation, and slow to change.

Given the evolutionary story, it is unsurprising that such a variety of terms have come to be used in this field: computer-based education, computer-aided learning/teaching, educational computing, information technology, educational superhighway, microelectronics education, digital technologies, information and communications technology (ICT), and educational technology.

The Breadth of Improvements Across the School Curriculum

In the early stages of introduction of microcomputers in schools, in the 1980s, the prime argument for their use was to develop the pupils' elementary computer-based skills in programming or computer literacy for the purpose of enhancing their employment opportunities (Passey 2014). As the software available in schools evolved and could be used more readily, without recourse to elementary programming, teaching focused on using so-called "productivity" tools (word-processing packages, elementary spreadsheets, and presentation packages such as Microsoft PowerPoint). Simplified versions of such packages were marketed (such as Edword, e.g., a word processor designed for use in schools) to improve accessibility even further.

Since the 1980s, ICT and digital, online educational technologies have had broad and continuing implications for the school curriculum. In the UK (England, Wales, and Northern Ireland), the Microelectronics Education Programme (MEP) (Fothergill 1981) set out to innovate, introducing electronics, microelectronics and its systems applications, including control technology, to what had been previously a craft-based technology subject. It updated computer studies from the mainframe era to the microcomputer generation, injecting computer-aided design, data logging, and data processing not only into computing but as educational tools into art and design, science, and mathematics. Word processing and other electronic office techniques

updated commercial studies and typewriting classes. The use of the computer as a means of storing and retrieving information in databases and the associated information systems was developed as a means of supporting learning and developing information-handling skills, initially in business studies, but more widely in a greater variety of subjects.

Furthermore, MEP promoted educational content development to assist learning (CAL, computer assisted learning) across the primary and secondary curriculum, as a guide to learning for the individual, as a learning aid for small groups of learners, or as a system for the whole class. Innovation was not limited to microcomputers but also to microelectronic devices such as robotic kits and computer peripherals for music, for art, for technology, and even for physical education and sports as well as turtle-based graphic devices to support elementary programming skills using the programming language Logo (Papert 1993).

It was the development of computer peripherals, special keyboards, and data entry devices which led to improvements in teaching for special educational needs by opening up access to computer-based learning for those with physical and other disabilities.

Government Responses to Computers and Educational Improvement

Not all regional or national education systems responded strategically to the challenges, threats, and opportunities of an emergent digital age, but where they did, they saw it initially as an attempt to build up industrially and commercially relevant skill - sets among young people through teaching *about* technology. The development of a rhetoric about using technology to improve the effectiveness of education – learning *with* and *through* – followed, and the debate about its relative success or failure in that regard persists today. The aim of the MEP, which inspired similar initiatives across Europe and beyond, was "to help schools to prepare children for life in a society

in which devices and systems based on microelectronics are commonplace and pervasive” (Fothergill 1981, p. 1). At that time, in the UK, there was no nationally prescribed curriculum, so it was necessary for MEP to promote and encourage improvement in schools “to respond to these changes by amending the content and approach of individual subjects in the curriculum and, in some cases, by developing new topics... with the dual aim of enriching the study of individual subjects and of familiarising pupils with the use of the microcomputer itself” (Fothergill 1981, p. 1).

The strategy for MEP went on to propose that “use should be made of the microcomputer to develop the individual pupil’s capacity for independent learning and information retrieval” (Fothergill 1981, p. 1), an aim which set sights directly on improving pedagogy in the classroom.

The UK government continued to intervene in educational improvement through technology by investing in 1998 with a £700 million development of a *National Grid for Learning* as an infrastructure and service for networked learning by connecting all 30,000 schools to the Internet by 2002 (Open for Learning, Open for Business 1998).

Its targets included:

- ensuring that serving teachers feel confident and are competent to teach ICT within the curriculum and that librarians are similarly trained;
- enabling school leavers to have a good understanding of ICT, *with measures in place for assessing their competence in it*; and
- making Britain a centre for excellence in the development of networked software content, and a *world leader in the export of learning services*. (Barnes 2001, p.1)

The purpose of national investment was evolving into an expectation that different models of “learning services” would emerge which might provide educational efficiencies as well as improvements.

The White Paper (Open for Learning, Open for Business 1998) sets out ways of ensuring a wider

use of existing software resources and getting a better return on investment by engaging educators in improving teaching, assessment, and learning through more innovative “e-learning” and also by modernizing the curriculum to be more adaptive in a digital world.

We need a concerted effort by the digital content industry, innovative educators and education researchers together, to demonstrate what the next generation of e-learning could be. (Open for Learning, Open for Business 1998, p. 12)

In summary, as technology and software design and development has advanced over the last four decades, and where system-wide access has been facilitated and promoted by national or regional education systems, so have the affordances which digital technology offers to educators in terms of educational applications. Limitations and risks which are, at times, associated with the use of educational technologies are sometimes blamed lazily on “the technology” (Cuban 2001). Yet when evaluation projects about the “failure of technology” in schools are examined closely, they expose examples of poor planning and decision-making in instructional design, poor pupil and classroom management, and inadequacies in pedagogic skills, or some combination. More often, the studies ask whether or not technologies enhance learning, rather than asking when and in what terms they might do so.

How Educational Technology Is Embedded in Schoolwork

Digital technologies are still today inherently disruptive to established patterns of working, and as a result, their uptake and impact on day-to-day practice depend upon innovative, creative users who are willing to review and revise their practices. The same spirit of innovation, creativity, and reflective open-mindedness is also essential for practitioners who engage in educational (school) improvement: it is unsurprising that effective educational uses of technology and effective self-evaluation leading to improvement can often be seen hand in hand.

This entry now summarizes, in turn, the three major ways in which digital technologies have come to be embedded productively, in ways which can, used well, improve life and work in schools:

- The role of technology in teaching, assessment, and learning.
- Its role in supporting the management and leadership of the school.
- Its use as a professional tool by teachers as practitioners.

When it comes to educational (school) improvement, the central factor in raising standards in attainment is the quality of learning as determined by the effectiveness of teaching and the response of the learners. Crucially, a focus on high standards in pedagogy needs to be underpinned by a high-quality institutional culture and leadership of learning which is conducive to improvement through effective self-evaluation based on first-hand evidence. Given the centrality of learning and teaching, more attention is given to these components in the rest of this entry.

The Role of Technology in Teaching, Assessment, and Learning

Digital technology applications have become embedded in education in ways which, when (i) of a high standard themselves and (ii) appropriately and effectively employed to a pedagogically high standard, can improve teaching and learning in at least five ways:

- Where the use of technology supports the progressive development of what might be referred to as “e-skills”.
- By supporting and developing the learners’ higher-order thinking skills, especially where the specification of such skills is set out explicitly in the regional or national curriculum.
- By facilitating both formative and summative assessments to enable learners to make judgments about their learning and their own progress.

- Where technological devices play an explicit role in aiding the access of learners with specific physical and special needs to learning and teaching.
- Where the technology itself is a central resource in specific subjects.

This section considers the first four of the bullet points above.

Evolving from ICT User (“e-Skills”) to Higher-Order Thinking Skills

Where the main pedagogic approach has been teaching *about* computers and how to use them, there have been evolving definitions of ICT skills: from programming to productivity, to problem-solving, to systems design, and eventually to an ICT skills framework.

There have been attempts, over many years, as the digital and online technologies advanced, to provide a certified award for skilled computer users and to address the current and future needs of business and the economy and for employers by ensuring that the sector is equipped to compete in the worldwide digital economy. Certification is usually validated by some form of national training organization, sector skills council, or national computer society. Sometimes it targets explicit skill shortage areas, such as e-skills for females, and sometimes attempts to be valid across countries, for example, the European Computer “Driving” License.

While they have a limited, prescribed value in the employment market, they have in common that they are neither well attuned to the curriculum, nor to teaching approaches in schools, nor do they attempt to address the progressive development of skills from the early years of schooling through to tertiary education.

School inspectors across the UK have seen a common problem in a failure of learners to progress in skills development arising from the ICT courses taught in the first years of secondary schooling (Ofsted 2013). In the UK at least, the primary school curriculum, taught by one teacher to a class for the course of a year, provides considerably good opportunities for productivity tools to be used to enhance thematic projects,

drawing across the whole curriculum in an integrated manner.

Together with a very healthy market in education software for schools, packages designed to help teach specific skills (language and mathematics skills) have enabled children in the classes of more innovative and creative teachers to develop their computer “literacy,” that is to say their ability to use computers, in an incremental and purposeful manner. The problem in secondary schools, however, has been that not all children making the transition to the early years of secondary education from different primary schools have had the same enriching experience. Too often, in response, secondary schools designed ICT skills courses, often taught by teachers with some level of qualification in computer science, in which they painstakingly taught pupils about the hardware components of computer systems and how to switch them on to make them work.

In order to counter this passive approach to teaching *about* computers, rather than to use computers as a tool for project-based approaches to teaching across the curriculum (*teaching with*), various ICT skills frameworks were developed, partly to expand the understanding of teachers about the affordances of ICT and partly to enable pupils to be accredited with competence in a wider skill set.

The NI Curriculum Council for Examinations and Assessment (CCEA) was the first of such bodies in the UK to identify a set of ICT user skills (CCEA 2018a) which is designed to be embedded in learning activities across the primary and the secondary curriculum, with examples of work which could be assessed and accredited in the school’s choice of subject contexts. CCEA identified a set of *capacities* in the application of ICT (at a higher level than operational skills) which were adaptable in any curriculum context, enabling the embedding of ICT to bring improvements directly to teaching and learning.

These interlinked capacities are codified as:

- **Explore:** the searching, finding, and using of information with digital tools to investigate and solve defined problems

- **Express:** the creative use of text, sound, music, and images such as developing a multimedia product
- **Exchange:** communicating online to share thinking and to develop ideas
- **Evaluate:** to think about how the application of technology might be improved, with a problem-solving focus
- **Exhibit:** using online communication to show-case the done work digitally

Furthermore, in a number of education systems, attempts have been made to define skills relating to the use of the technology in *higher-order* processes, which relate to learning itself and not just the ability to use a computer for prescribed tasks.

Where a regional or national curriculum defines the skills and competences which are central to learning and working, for example, *thinking skills* and *personal capabilities*, these align much more closely to the productivity uses of ICT software and tools. Thinking skills and personal capabilities can comprise managing information; thinking, problem-solving, and decision-making; being creative; working with others; and self-management (CCEA 2018a).

Where the development of thinking skills and personal capabilities is an integral and required part of the curriculum, the development of these skills can help pupils to think critically and creatively. They can help them to develop personal and interpersonal skills and dispositions in a changing world, especially when learners use digital tools that help them to go beyond acquiring knowledge. In the NI curriculum, for example, in order to develop the learners’ thinking skills, teachers are required to design learning experiences that will encourage pupils to engage in better quality thinking. Tasks are designed to enable pupils to search for meaning, apply ideas, analyze patterns and relationships, create and design something new, and monitor and evaluate their progress. To develop the learners’ personal capabilities, the teacher can create opportunities for them to experiment with ideas, take initiative, learn from mistakes, work collaboratively, and become more self-directed in their learning.

Thinking skills can be facilitated readily by using productivity, critical and pathway planning and research tools, mind-mapping tools, databases and spreadsheets, information management and artificial intelligence systems, communication media, group work tools, and information assets. They include activities which can involve:

- Sequencing, ordering, classifying, and making comparisons
- Making predictions, examining evidence, distinguishing fact from opinion
- Making links between cause and effect
- Justifying methods, opinions, and conclusions
- Generating possible solutions, trying out alternative approaches, evaluating outcomes
- Examining options, weighing up pros and cons
- Using different types of questions
- Making connections between learning in different contexts

The learning outcome is intended to “show deeper understanding by thinking critically and flexibly, solving problems and making informed decisions” (CCEA 2018b). In this context, managing information involves asking, accessing, evaluating and selecting, being alert to error, recording, and integrating quantitative data and qualitative information. It can include:

- Asking focused questions
- Planning and setting goals, breaking tasks into sub-tasks
- Using one’s own and others’ ideas to locate sources of information
- Selecting, classifying, comparing, and evaluating information
- Selecting the most appropriate method for a task
- Using a range of methods for collating, recording, and representing information

Over time, as it becomes apparent that low-level skill sets in employment are being made redundant through automation, government reports recognize that a premium is placed on more rapid progression to higher-order skills and thinking capabilities in the education system.

For example, the UK House of Lords July 2015 report *Make or Break: The UK’s Digital Future* highlights the impact of changing technology on the labour market and warns that education in the UK was not addressing the significant digital skills shortage in business and industry. It identified that females are underrepresented in digital jobs and there are insufficient apprenticeships and a shortage of medium- and high-level digital skills. In response, some of the recommendations in the report are that digital literacy should be taught alongside and complement numeracy and literacy. The report makes reference to the UK Digital Skills Taskforce’s three-band definition of different skills levels: digital citizen, digital worker, and digital maker, along with the UK Forum for Computing Education’s application of the definitions to the workforce (Department for Business, Innovation and Skills and Department for Culture, Media and Sport 2016).

The concepts behind the three broad tiers of digital skills can be applied to the context of a learner within a school setting. CCEA, for example, sets out that it wants to ensure that learners in schools could become:

- Digital citizens, with the skills that will enable them to take part in digital aspects of society, to communicate, to be informed, to participate, to buy and sell, to share, and to work safely and without hindrance.
- Digital workers, who are able to use tools, to process, to analyze, and to apply their digital skills to further their learning or in a work-related setting.
- Digital makers, who are starting to design, to build solutions, to create, and to invent and build.

CCEA recognized that merely being able to use digital devices is not enough to gain some forms of employment in the future. In fact, being able to use devices will be the basic standard required in any future employment, and increasingly young people will need to learn how to build things with digital devices. They will need not just to be able to program or code, they will need to

Computers and Educational Improvement, Fig. 1 Digital skills curriculum and qualifications framework

think logically and solve problems with different digital products. They will all need to become digital makers and workers.

CCEA developed a framework (Fig. 1) to show the clear progression of these digital skills for learners from the early years and foundation stage of education to public examination level post-16 and beyond into tertiary education.

Our framework is attempting to integrate digital skills across the education system, building thinking skills into the process of learning about digital devices and creating qualifications that are unique to Northern Ireland. (CCEA 2018c)

How Technology Can Be Embedded in Ways That Can Raise Pedagogic Standards

If technology is to make a difference, standards need to be high in five underpinning dimensions of provision:

- (i) Infrastructure provision
- (ii) Technical standards

- (iii) Content development
- (iv) Pedagogic affordances and practice
- (v) Institutional development

Other entries deal in detail with high standards in the technical delivery platforms – the hardware used, the underpinning network infrastructure, and high-quality software content/curriculum resources – the software used.

But successful educational improvement also depends on the culture and leadership of the institution – the school – and especially on the understanding and capacity of the leaders and staff in the processes of educational self-evaluation, based upon first-hand evidence, which leads to improvement.

However, the pedagogic decisions by teachers on what, when, and how to use digital/software assets depend on a good understanding of the affordances of the selected asset and will determine whether or not learning may improve by addressing successfully the identified teaching

challenge and the learning barrier or interest, in the way in which learner, teacher, and resource application interact.

Pedagogic quality refers to the quality of teaching, learning, and assessment activity using technology-based assets – resources and tools (Anderson and McCormick 2006). The quality of the content itself underpins the pedagogic quality, but it *affords*, rather than determines, pedagogic quality. The extent to which it leads to good pedagogic quality depends on the decisions and behaviour of teachers in selecting the appropriate resource/asset, designing and preparing for the interaction, and the understanding and skill of the learners throughout their engagement.

The axiom is: the greater affordance in the content design, the greater the scope for pedagogic quality; the narrower the resource design, the greater the understanding and the more decision-making which is required from the practitioner in designing, preparing, and offering the learning/teaching activity.

This can be understood by considering a number of affordance subcategories:

- (i) The **match of the resource to the curriculum**: the design of the resource needs to have clear objectives, which are relevant to the purpose, and enables the learner to engage in relevant learning activities which are supported by the nature of the assessment afforded.
- (ii) **Inclusion**: the resource serves the target user well; does not in its design (such as the language level) exclude any learner; accommodates to a range of different types of special need and any physical disability; and is inclusive to a range of social and ethnic diversity and gender.
- (iii) **Ease of use**: the resource is intuitive in use, needing minimal guidance; makes appropriate assumptions about the user's ICT skills; and is accessible/transparent to use.
- (iv) **Learner engagement**: the design engages the learner by being purposeful, enjoyable, supportive, and encouraging and creates a good ethos – a good atmosphere and experience for learning; it is flexibly designed and can be used in creative ways from very simple to very complex; it is readily in the control of the learner by being largely transparent to use in ways which do not interfere with the learning purpose; and it integrates easily with other software tools or assets.
- (v) **Effective learning**: it takes innovative approaches and makes effective use of digital affordances; it supports a range of uses allowing a good match to how the learner approaches learning; it supports diverse learning styles while extending the users' repertoire of learning approaches; it may accommodate a didactic approach to teaching as well as independent use by the learner; its activities facilitate collaborative learning and contribute to problem-solving skills and sharing and explaining information; and it acts as a catalyst for creative and group thinking and as a tool "to think with."
- (vi) **Effective outcomes**: it promotes the characteristics of agency by the learner; it engages the learner in thinking (even where the learner is just responding by clicking a mouse); it affords control of pace and control of the paths through the material; and it enables and encourages metacognitive thinking (e.g., by asking the learner to reflect on their responses or approaches to the activity).
- (vii) **Authentic materials**: any material content should be a good representation of the ideas or situations that are present in the world outside (in other words, an element of realism without necessarily being realistic), and the materials should be appropriate to the personal orientations, prior knowledge, and experience of the learner.
- (viii) **Formative assessment**: the assessment element should support learning by providing rapid feedback on how to improve and opportunities for peer assessment and self-assessment.
- (ix) **Summative assessment**: the assessment provides grading/scores which are valid

and reliable; are comprehensible; deal with a range of achievement; and are non-adverse by not creating a negative response from the learner.

- (x) **Value for money:** given the inherent costs of using an ICT-based approach, does it have the potential to demonstrate cost-benefits or other indicators of value for money over any other approach?

The Role of Computers in Supporting the Management and Leadership of the School

Computer applications play an indispensable role in school administration, as they do in any enterprise. Over time, the separate administrative database applications have been developed into integrated, whole-school systems and therefore have evolved from helping senior staff manage separate aspects of the daily running of the school to helping all staff to drive improvement by supporting the integration of first-hand evidence about the effectiveness of teaching and learning for the purposes of internal and external accountability and leadership decision-making. Systems provide evidence to support decision-making not only by leaders but also by governors, for external accountability to the school service and for timely and relevant information for parents and the school community.

Schools hold increasingly detailed information about staff and students. For the student, this is not only about their background circumstances which impact on their engagement but also in tracking their progress through a school in terms of their attendance and behavior, and especially by turning assessment and test data into usable information which can help set performance targets for learners, taking their pastoral needs into account in supporting their learning, and identifying and making necessary interventions through personal learning plans.

Technology has made it easier for teaching and pastoral care to come out of their separate silos and merge, to the benefit of the learner. Integrated

management systems mean that the systems can be set to maintain elementary monitoring across the different data sets about each learner, with flags set to draw the attention of the relevant staff when agreed parameters (e.g., for attendance, behavior, test performance, costs, and so on) reach critical levels which merit intervention.

Costs drawn from the financial data of a secondary school can be correlated across the deployment of staff to provide specific subjects, the uptake of those subjects, and the relative examination success to determine the cost-benefits of the school curriculum. Similar correlations can be done to assess the cost-benefit analysis and the value added by the deployment of classroom assistants.

The performance management of teachers is also assisted by analyzing the performance of class and student groups, comparing the progress of and outcomes for similar cohorts in similar subjects to help inform decisions about the best way of deploying and timetabling the variation of expertise across the school workforce and providing targeted support to teachers where there may be underperformance and for their necessary improvement as professionals.

The Use of Digital and Online Technology Professional Tools by Teachers as Practitioners

Teachers themselves, and especially as professionals who are engaged in improvement, come to rely on online technologies in their day-to-day planning and preparation of lessons, identifying teaching and learning resources (increasingly using digital assets) and in evaluating the progress of learners through the evidence of tests and online questionnaires for their learners.

Management information systems are also used to support group management tasks, for example, jointly authoring and managing the complete cycle of school and department/phase developmental and action planning. Online group memberships can be managed across the organization; shared network folders and shared

writing of planning documents can strengthen collegial cooperation and collaborative working in a practical way. The systems provide a means of monitoring, recording and self-evaluation processes, and identification of priorities and actions through to detailed activity allocation and tracking of progress and achievement.

Management information systems also provide tools for creating and analyzing online questionnaires which are used for a variety of consultative and evaluation purposes, for example, the determination of collective views on policy; assessment of attitudes to change across staff groups; consultation with parents and the wider community on their views of the effectiveness of the organization; and questionnaires for learners to test their progress in curriculum-based knowledge and skills and to evaluate their views as learners about the effectiveness of classroom approaches adopted by the teachers and the response to initiatives to promote their wellbeing and protect their welfare.

With some half of the teaching workforce in many education services being of the age where they have used computers and the Internet and have learned, worked, and socialized online since they were students, they do not countenance any other way of working. Unsurprisingly, they turn to social networks in seeking contributions to their own professional learning and development, sharing ideas and resources, and discussing solutions to specific teaching challenges. Webinars and online workshops, some of which offer certificates of participation, credits, or digital badges, provide opportunities to learn with educators from universities and specialist teaching organizations and to network with and learn from the experiences of other teachers all over the world, who discuss how to engage learners, manage the classroom, and create engaging learning experiences. Some online environments are more structured. They provide teaching related to curriculum content or skills such as digital storytelling, data visualization, and critical media use to support all curriculum areas.

In some education systems, professional teacher organizations, such as teaching councils and professional bodies, have created online

portfolios for teachers to enable them to create, to control, and, if they wish, to share their portfolio for their own professional learning and career progression purpose.

The developments described here represent a more fundamental underlying shift in teacher professional learning from the dependency culture of teacher in-service education courses to the growth of self-sustaining communities of practice.

Those teachers who are more innovative in their practice, make use of online learning environments to publish their course contents, teaching materials, study resources, including multimedia productions, and self-assessment quizzes for their pupils to access either in the school or at home. They employ closed discussion boards, instant messaging, or email groups as a form of socio-educational media to host teaching exchanges and discussions with course groups and classes.

Once teachers have published their courses online, some begin to explore improved pedagogic models such as blended learning and flipped learning (where some of the teaching takes place online). However, teaching online requires specific teaching skills and research into the most effective responses into challenges about how to build an effective and safe online community, how to relate it to classroom teaching, how to foster active participation and engagement by learners, how to design and manage formative and summative assessment online, and how to strike the most effective study/life balance and to manage the risks of learning performance-induced stress.

Conclusion

In a powerful combination of ways, the various and very different roles of technology in schools, which were used initially as separate tools (for administration, for teaching, for testing, and for learning), have collectively changed all aspects of teaching professionalism. Initially, they enhanced existing provision (and in some schools that is still all that they do), but elsewhere, they lead to change and they shape whole-school improvement.

Over the past four decades, different applications of digital technology in schools have spread out like a series of distinct ripple patterns emanating from separate pebbles thrown into the metaphorical “pool” of school life and work. The ripples have intersected and are creating a dynamically holistic disturbance which is more than just “disruptive” to the surface of life in schools. They are increasingly affecting the underlying currents and wave patterns of what skills and knowledge need to be learnt, what it means to teach and to assess learning, and, fundamentally, what “learning” itself might mean in a digital world. It is impossible now to think of schools, as complex organizations, dealing with the complexities of learning and teaching in a social environment, highly dependent on information/data and on developing the necessary skills (for learner, teacher and leader alike) of information-informed decision-making, operating effectively without the multifaceted ways in which technology supports the endeavor of schools, leading to improvement in the interests of the learner.

Definition

Computers in Education in Developing Countries: Managerial issues include the inclusiveness of computers in education program for different institutions and different localities, the cost involved, transferability of the affordance of the technology implemented, and the social effects for the viability of the innovation.

Introduction

Information communications technology (ICT) has the potential to increase the productivity and economic growth of a country. The World Bank Group (WBG) (2012) has been encouraging innovations in ICT as it seems to increase a country's competitiveness and enable economic opportunities for more IT-based services industry within the country. This is especially significant for countries with poorer economies. ICT products and services which cater directly to the

society in these countries enable the diffusion of technology across the economy, thus accelerating economic growth and building human capital (Lubin 2018; WBG 2012; World Economic Forum 2015).

In Malaysia, the ICT revolution came about when the Multimedia Super Corridor (MSC) was established in 1996 with the aim of building a sustainable ICT industry (Economic Planning Unit (EPU) 2001). By 2005, a total of 1,421 companies with MSC status were involved in the ICT industry, thus increasing the job opportunities in this sector (EPU 2006). By 2015, ICT-related industries, including e-commerce, contributed to 16.8% of the gross domestic product (EPU 2015). Malaysia has shown exemplary growth in the ICT sector which has in turn impacted economic growth and human capital development. This was also confirmed in a study which recorded ICT investment carried out by the private and public sectors during the period 1992 to 2006 which had a significant impact on Malaysia's economic growth (Kuppusamy et al. 2009). Hence, ICT has impacted economic growth and human capital development in Malaysia. The success of Malaysia and other developing countries in developing this sector has been the rationale for poorer countries to prioritize on ICT and to introduce computers in education.

However, ICT may not contribute to the overall economic growth of a country. The World Economic Forum (2015) reports that only rich countries seem to benefit from ICT for innovation, while in poorer countries, this results in a wider digital divide. In the poorer countries, the portion of society which have been induced by technological innovation have benefited and advanced in skills, but the rest of society may not have even acquired the minimum knowledge and skills and are left behind. Hence, the reported progress of a developing country in ICT may not indicate that a digital divide still exists and that there is a non-inclusive growth in human capacity (WBG 2012). A more inclusive program to involve all levels of society in human capital development for ICT is required.

In this entry, the definition of the developing countries is based on Lubin's (2018) definition and refers to countries which are less advanced industrially, have smaller economies than developed countries, and may have populations with lower levels of education, life expectancy, and household income. Lubin (2018) also identified that the more critical group of developing countries are the smaller countries with small populations and low-income status which represent a large portion of the world's independent states. These small developing countries are heterogeneous in their cultural heritage, languages, identities, and behaviors and have much to contribute in terms of educational technology research on implementation, policies, and practices of educational technology (Lubin 2018).

At present, literature on these developing countries is lacking, perhaps due to the smaller population of these countries (Lubin 2018). At the same time, implementing computers in education programs does not come without any problems. This entry hopes to outline some of the managerial issues which may arise in the implementation of computers in education program, such as inclusiveness, cost of investment for the technology and the social environment, building human capacity, as well as policies for designing the instructional environment and developing the infrastructure. Malaysia is used as an example for sharing efforts made during the implementation of their computers in education program, via the Smart School program.

Inclusive ICT Education Programs

The key to developing productivity in ICT lies in developing human capital for the industry. Hence, an inclusive education related to ICT should be emphasized. Education technology is seen as a solution to address the problem of the digital divide and non-inclusive growth in human capacity in developing countries. Ensuring that the computers in education program were provided at all levels of education, primary and secondary, as well in rural and urban areas,

would reduce the digital divide. Hence, introducing computers in education may spur social and economic growth to alleviate the country from poverty to a more developed status.

In the case of Malaysia, the Smart School Pilot Project was implemented for 88 schools in 1999 and rolled out through the "Making of Schools Smart (*Pembestarian*) Programme" at the end of the pilot project (Alias et al. 2013). The Smart School program was inclusive as all 10,000 schools in Malaysia were equipped with laptops, computers, and instructional materials through various ICT-related programs such as the School Laboratory Project and the Teaching of Mathematics and Science in English (Alias et al. 2013). The aim of these programs was to develop a technology-literate workforce for the information age. The program was inclusive and aimed to reduce the digital divide among the rural and urban schools.

The Malaysian government has seen the return in investment in education as the number of jobs in the ICT sector has increased. Documentation of the numbers of workers in the following ICT sectors from 2000 to 2002 indicates an increase in ICT-related jobs: software consultancy and supply, 80.6% (7,642 to 13,799); data processing services, 226.9% (809 to 2,645); database activities, 44.7% (472 to 683); and maintenance and repair of computers, 127.7% (628 to 1,430) (Kuppusamy et al. 2009).

Implementing computers in education programs has benefits for the country as the technology-literate workforce can bring about economic growth and productivity for the nation. However, consideration has to be made to ensure that human capacity development is inclusive and provided to all layers of society. This is so as not to increase the digital divide between the "haves and" the "haves-not." Developing countries do not want to be left behind in the ICT revolution in the globally competitive world, but policy-makers and managers in these countries should be aware of issues which may arise (Lubin 2018). While providing inclusive computers in education program may be necessary for economic growth, the concern is the high cost of investment in such programs.

Cost of Investment

There is a substantial investment involved when implementing computers for education. The Smart School Pilot Project (1996–2002), which was a fully integrated solution encompassing instructional materials (courseware), hardware, and change management, cost the government of Malaysia USD 78 million (RM 300 million) (Ng 2010). And this pilot project involved 88 pilot schools. Rolling out the solution to the other 10,000 schools had to have most cost-effective measures. The computer lab model (School Laboratory Project) and laptops for teachers involved in the Teaching of Mathematics and Science in English were completed in phases (Alias et al. 2013). Many developing countries might not be able to afford such high costs and need to depend on other assistance.

Monetary and other assistance for modernizing education in developing countries have come from developed countries and international organizations such as the World Bank. In many cases, the developing countries have no barriers and welcome the international assistance from the richer countries without question (Lubin 2018; WBG 2012). Sometimes, hardware such as computers and servers are provided as aid for computers for education programs as one-off projects and may not come with support for the use of the hardware. In accepting these aids, or even when considering the purchase of a technological solution, the policy-makers in developing countries need to consider the effects of the implementation and whether there is sufficient support for the hardware and instructional materials provided.

Hence, when considering the solution for the computers in education program, the question that managers implementing technology need to ask is whether similar solutions implemented previously in a developed country would have the same affordances and beneficial outcomes in the developing country.

Transfer of Affordances of the Technology

The first consideration is whether there is *innate transferability of technological affordances* (Lubin 2018). A developed country may have

been using a specific technology successfully. However, when the same hardware was provided to the developing country, it may not be useful. As an extreme case, computers provided to a developing country with irregular electrical supply or slow Internet speeds in some parts of the country might not be switched on, and the software applications which require a broadband connectivity, might not be used.

Malaysia had addressed this problem of *innate transferability of technological affordances* in these two aspects. There are remote areas in Malaysia with no electrical supply. The computers and laptops provided to schools would not be useful without electricity, and hence its usefulness would not be transferable to these schools. The problem of the lack of electrical supply was solved by providing diesel-driven generator sets for remote schools with irregular electrical supply. Similarly, Internet connectivity was a problem in remote areas. In order to use the virtual learning environment (FrogVLE) provided for schools, Internet connectivity was required. Hence, the affordances of the FrogVLE were not transferable without Internet access. In resolving the problem of Internet connectivity, the government provided 1BestariNet since 2012, for broadband connectivity to all schools, with schools having an option of undertaking additional Internet service providers with network connectivity in these specific areas.

In addition to the hardware, managers may also need to consider the *innate transferability of technological affordances* of the software applications and instructional materials provided. The delivery of these applications and materials should be suitable for the needs of the students in the developing country. Some software applications and instructional materials (courseware and e-materials) may be very interactive and stimulating for learners but are delivered online. Broadband Internet connectivity may be required for these software applications and materials, which may be a problem in developing countries. An alternative to Internet access may be to deliver these applications by installing them on the computer or servers or delivering on CD-ROMs and other devices.

In Malaysia, a large number of interactive courseware had been produced, customized to the Malaysian culture and context, and verified by teachers during the Smart School Pilot Project and the Teaching of Mathematics and Science in English program (Alias et al. 2013). These materials were supplied to all schools on CD-ROMs since 2005 as part of the Teaching of Mathematics and Science in English program to avoid online delivery and lack of Internet connectivity. However, currently e-materials are also provided and hosted on online platforms for schools to access when Internet connectivity was available. In addition, teachers are also required to develop their own instructional materials on the “sites” in the FrogVLE. This variety of delivery methods ensured that the affordances of the software applications and instructional materials were *transferable* to different contexts.

Social Effect on the Users

The next consideration is whether there is *viability of the technological innovation* (Lubin 2018). In addition to the technology (hardware and software) provided, the users and society in general need to be considered. In implementing the technology solution in the developing country, policy-makers and managers would need to consider the social effect on students, teachers, and administrators as a result of the innovation. Would the social effect, and the acceptance level, be the same as originally envisioned when it was implemented in the developed country?

Managers implementing computers in education programs in developing countries need to consider the viability of the program before implementation. For example, research has shown that when only instructional materials such as textbooks are provided, these do not necessarily improve learning (Glewwe et al. 2009; Kremer et al. 2013; Pedró 2018). Instead, when instructional materials provided are supported with an applicable instructional model and a teacher training program, it becomes more effective (Pedró 2018). Hence, when computers in education are implemented in

developing countries, managers need to consider having an appropriate teacher training program to develop human capacity. This is discussed further in the later section.

In addition to providing training programs for teachers, consideration on whether these materials are suitably adapted to the culture, morals, customs, and perhaps even language of the developing country. If the technology innovation is not suitable for use in the target culture of the developing country, it may not be accepted well by teachers and parents. As an example, the Ministry of Education Malaysia has attempted to introduce mobile phones for teaching and learning in schools in 2005 and 2017. However, there have been objections from teachers on the use of this device in school as it was claimed that disciplinary problems would arise. Hence, the *viability* of the use of this device for teaching and learning was in question, and innovation related to this device might not be accepted by teachers.

Hence, when resources and computers are provided, they can only have an impact on education when there is a commitment from teachers and parents on the usefulness of the resource and the technology. In addition, teachers need to believe that the resources can be adapted to the individual student's level and result in changes in student's learning experience (Pedró 2018). Managers in developing countries need to consider the development of human capacity for the acceptance on the use of computers in education. The acceptance and support for building human capacity are discussed next.

Building Human Capacity

The *viability of a technological innovation* depends on the human factor. Teachers are most directly involved in the instructional change when computers are used in education and they can most likely determine the success or failure of the program. However, teachers can only perform at their best when instructional leaders in their school support the change. Hence, developing human capacity among teachers and

instructional leaders is important for the viability of the program.

Pedagogy Matters

When computers are used for education, the way teachers teach and the instructional materials which are used may need to change. The traditional forms of teaching differ from a blended or online model of instruction using computers. Hence, the instructional role of the teacher and the pedagogy, which is the practice of teaching employed, may need to change.

In some computer in education programs, teachers are provided with instructional materials, and hence, teachers need to plan their teaching so as to provide meaningful educational experiences for their students learning. However, when implementing a new technological innovation, does it make provisions for teachers to be well trained in the program? Teachers in developing countries may not have been trained to integrate technology in their instruction as they may not have had sufficient reason for this form of training, seeing as schools were not provided with such equipment. As a result, these teachers, when confronted with computers and electronic instructional materials, do not know how to best use these materials and feel at a loss when using them (Pedró 2018). Hence, managers need to ensure that when a computer in education program is implemented, teachers are provided sufficient training in the pedagogies for use with computers.

Providing the appropriate training ensures effective use of technology. McEwan (2015) provides empirical evidence that in developing countries, effective use of technology for teaching is accompanied by appropriate teacher training. This would ensure that students receive the best impact on their learning. Hence, when implementing computers in education programs, the right pedagogy which would most help teachers in using the new technology needs to be identified (Pedró 2018). However, applying the suitable perspective of pedagogy also depends on which applications and instructional materials will be used.

There are several perspectives of pedagogy which can be taken when using computers in

education. The behaviorist perspective assumes the transmission model of instruction and uses the *stimulus-response* interaction, with teacher questioning and students answering, accompanied by *immediate feedback* for reinforcement (Bower 2017). This perspective seemed to be used in many learning courseware in the Malaysian context, where a mastery learning approach seemed to be used. On the other hand, the cognitivist perspective looks at the mental processes in forming and reorganizing knowledge, using an information processing framework (Bower 2017). Some courseware also use this approach as learners are required to compare, identify similarities and differences, and make inferences from the information presented.

On the other hand, the constructivism perspective is based on the individual actively constructing his own knowledge, through processes of *assimilation* and *accommodation* (Bower 2017). The role of the teacher in the constructivist learning environment is to design learning environments for the learner to discover principles (Bruner 1990). The social constructivist perspective extends on the constructivist perspective by including cultural and social elements in the learning process (Bower 2017). Learning is facilitated through discussions and negotiation as the teacher scaffolds the learner toward achieving expertise (Vygotsky 1978). In the Malaysian context, the FrogVLE enables a collaborative form of learning using online discussion in a social constructivist perspective.

Connectivism is another perspective where learning knowledge is a networked phenomenon, and to be effective, the learning networks need to be decentralized, distributed, and dynamic in an organic and rhizomatic way (Bower 2017). Connectivist pedagogies help people develop digital and critical literacies needed to survive in a networked world (Siemens 2005). There are many specific pedagogical approaches which fall under the above perspectives, and have been used with technology, and may be beneficial for teachers in working with computers such as collaborative learning, problem-based learning, inquiry-based learning, constructionist

learning, design-based learning, and game-based learning (Bower 2017). The teacher would need to consider the instructional materials to be used when implementing computers in education program and to use the appropriate pedagogy for designing the learning environment suitable for his students.

In Malaysia, teacher training had focused on constructivist and inquiry-based learning in 1996, before deliverables of the Smart School Pilot Project was deployed in schools. The Smart School Conceptual Blueprint indicated that a variety of resources could be used for learning, including realia, and stressed on encouraging students' multiple intelligences (Ministry of Education Malaysia 1997). However, when the Smart School Integrated Solution was deployed with instructional materials (courseware) for self-paced, self-accessed, and self-directed learning, there was still some ambiguity on the use of these materials. One reason might be because the pedagogical perspectives in some of the courseware differed from teachers' perspectives. Another reason was that teachers who were originally trained for the pilot schools had transferred to different schools when actual deployment was done in 2000. Hence, continuous retraining efforts had to be conducted for more effective implementation.

Managers of computers in education program need to be aware of such issues regarding training. Teachers should be provided training in the pedagogies for computers in education and be exposed to instructional models which can be used for teaching. At the same time, efforts for retraining and upskilling teachers from time to time need to be provided.

Acceptance of New Technologies

Introducing an innovative computer in education program may require teachers to acquire new pedagogies. Teachers no longer need to be traditional transmitters of knowledge but instead are required to be facilitators for students' learning. Some teachers may find this change to be too abrupt and perceive the introduction of this change as a threat to their existing practices. Managers of computers in education program

need to be aware of this perception among teachers and adopt the right attitude to address this change.

As mentioned earlier, the viability and success of a program depend on the teachers who are the implementers and would ensure that successful learning environments could be designed. However, many a time teachers seem to be at the receiving end of the technology and have to implement the program without assistance and support given for the use of the technology. Coupled with the lack of confidence and belief in the technology, teachers who are not convinced on the usefulness of technology would reject it.

The theory of reasoned behavior notes that teachers' beliefs would motivate and influence the attitude toward the technology and the intent to use the technology (Davis et al. 1989). Hence, the perception of the ease of use of the technology and the relevance of the technology to solve the problem would determine whether teachers make use of the technology.

This means that for teachers to perceive the technology as *easy to use*, they should have sufficient training in the use of the technology itself. This means developing professional or personal skills such as having a technical command of the computer and being able to set up the computer for use (Pedró 2018). Hence, managers would have to determine that sufficient technology skills are developed among teachers involved. Teachers who have technology skills are more likely to perceive the innovation as *easy to use*.

Secondly, is the *relevance* of the technology to address instructional problems. In order for teachers to perceive the relevance and validity of the solution, teachers should be informed and made aware of the benefits of implementing the innovation. For computers in education program, benefits which may arise are the increase in students' motivation and improved academic performance (Pedró 2018).

Managers need to ensure that instructional leaders share the vision of the change that the innovation would bring and would be able to communicate this vision and lead other teachers toward successful implementation. The

instructional leader who can be the school head or a technology leader in the school needs to continuously communicate the goals of the program and the change efforts to the entire school community so that they are made aware of the benefits of the change (Abdullah et al. 2013). Only in this way, the school community would develop the right attitude toward the change. The vision of the innovation should also be communicated to parents so that they would be aware of the innovation and support the implementation.

Managers should ensure that there were suitable supports for teachers, both in using technology and in addressing change. Communities of practice in the use of technology and for teaching with technology can provide support when an innovation is implemented.

In conclusion, development of human capacities has to consider the teachers' needs. Teachers would be more convinced if the innovation was able to show a long-term effect on the students' results and to make teachers' work more efficient (Pedró 2018; Van Velzen 2013). Teachers also needed to see a lot of different situations in which students were using the particular innovation and methodology and also needed comparisons to be made with other methods currently being used (Pedró 2018; Van Velzen 2013). Only when teachers had the right attitude toward the innovation and were convinced of the benefits of the innovation, there would be more chances of viability of the innovation (Pedró 2018). In order to support teachers' implementation of the innovation, there has to be the right policies in place so that teachers are aware that what they are implementing meets the desired vision of the organization.

Policies

The World Bank (2012) notes that developing countries should build policies to strengthen skills and competencies among the population, to build capacity, and to improve the technological infrastructure and services, which include broadband connectivity. The following discussion builds on policies related to building the skills

and competencies among teachers to teach in the new instructional environment and policies related to infrastructure development.

The Instructional Environment

The use of computers in education changes the teaching and learning processes. In order to support these changes, there will need to be additional policies in place, or replacement of current policies, so as to ensure the vision of the innovation will be maintained. Salas-Pilco and Law (2018) reviewed ICT policy initiatives in small developing countries and found that most of these countries had policies which were stated as simple strategies, programs, or projects rather than clearly defined, system-wide policies. A favorable ICT policy needs to be a formal ICT policy developed as part of a national plan. The implementation of the Smart School initiative in Malaysia was part of a national plan in developing the MSC nationwide. This ensured the success of the project. In addition, policies were identified in the educational system to ensure that a systematic change in policies was initiated for the implementation of the Smart School Integrated Solution. Policy changes included the acceptance of online attendance, lesson planning, reporting, and assessment.

Salas-Pilco and Law (2018) identified that most of the policies of small developing countries focused only on integrating ICT into the curriculum for all subjects. In addition, the four different aspects of ICT in education that was considered were for ICT in the curricula, teacher training, school infrastructure and connectivity, and development of digital resources. The countries reviewed did not have a separate subject for ICT.

Hinostroza (2018) outlined the challenges which developing countries need to address in the policies on integrating ICT into the curriculum. He states that the policies would need to consider the definition of the set of digital skills that teachers and students need to acquire, the integration of these skills in the curriculum, strategies to ensure that teachers and students develop these skills, and the pedagogical methods that take advantage of these skills in the teaching and learning of traditional subject

areas (Hinostroza 2018). Hence, managers should consider that policies to address these issues need to be defined.

Teachers require new competencies to address the change that teaching with computers brings. Hinostroza (2018) states that challenges in teachers managing the integration of computers for learning and managing the learning take place both inside and outside the classroom, as well as ethical and legal issues regarding the use of online resources among students and teachers. For this purpose, teachers require a new set of digital competencies such as the UNESCO (2011) ICT Competency Framework for Teachers. As the curriculum and the use of digital contents and tools may also need to change, relevant policies need to be put into place to assist these changes (Hinostroza 2018). The implementation of computers in education should not be just adopting the technology for modernization of education but for an overall systemic change in the education system.

Infrastructure Development

ICT has the potential to develop the capacities of the workforce in developing countries. However many of these developing countries do not have a strong technological infrastructure in terms of reliable electricity supply and Internet connectivity (Salas-Pilco and Law 2018). However, the cost of providing for ICT infrastructure is high.

Developing countries may need to look at new possibilities of providing infrastructure for computers in education. Salas-Pilco and Law (2018) suggest the following: (1) establishing smart partnerships with organizations, which may be private, either international/regional, and also with other related institutions to implement computers in education programs, (2) establishing leverage on international support, and (3) establishing collaborations between countries.

Among the organizations which have provided funding for improving capacity in ICT are UNESCO and the World Bank, and private companies such as Intel® and Microsoft® have also provided support in providing training materials and developing capacities among teachers

for computer in education (WBG 2012). Managers of computers in education program should negotiate for assistance and support from these organizations.

Another consideration for building infrastructure within a developing country is for existing companies in the developing country to have links with technology firms in developed markets. This is so that talent and infrastructure can be built in the developing country, while the firm in the developed country can grow their businesses internationally (WBG 2012). Other voluntary collaborative communities can be sourced out to develop and support existing networks in the developing country. One such community is MobileMonday, an open community platform of mobile industry visionaries, developers, and influential individuals, which originated in Helsinki (WBG 2012).

Strategic public investments in the development of ICT infrastructure should be considered. Many developing countries may lack private investment, despite having sound policies and regulatory frameworks. Hence, developing public-private partnerships (PPPs) for providing high-speed Internet to improve global broadband connectivity can benefit the country (WBG 2012). PPPs, when tailored to the country's context and ICT sector specificities, are a practical solution to building the infrastructure.

Managers of computers in education program need to be innovative in their approach in providing the infrastructure which is needed in small developing countries. Ensuring that the proper policies are put in place can ensure the development of the country can be leveraged on these policies.

Conclusion

Computers in education programs can be employed for building human capital in ICT. However, implementing such programs cannot be undertaken without proper consideration and planning. The managers of computers in education programs in developing countries need to consider providing for inclusive programs to

reduce the digital divide among the different levels of society. The high cost of investment of an inclusive program must be balanced with the benefits for the country. However, care must be taken before adopting technologies and programs which have been implemented in a developed country, because issues such as the transferability of the affordance of technology and the social effects for the viability of the innovation need to be considered. Building human capacity is important for the viability of the innovation, and training for the appropriate pedagogy, technical skills, and acceptance of the technology needs to be provided. Policies that are in place for designing the instructional environment using ICT and developing the infrastructure can provide leverage for the success of computers in education program. Hence, managers have to ensure that proper planning and thought go into the implementation of computers in education program, so as to be successful and able to contribute to the productivity and economic growth of a developing country.

Summary

The information communications technology (ICT) industry holds the promise of improving a country's productivity and economic growth. Hence, developing countries have been jumping on the bandwagon, implementing computers in education programs for building human capacity in ICT. However, implementing computers in education requires significant amount of planning. Policy-makers and managers would have to consider several issues. One issue is to ensure that such programs are inclusive for all levels of society, primary and secondary schools as well as rural and urban areas. This is so as to reduce the digital divide among these levels of society. However, the cost of investment of inclusive computers in education program is high. One way to reduce costs is to adopt programs which have already been implemented elsewhere, perhaps in a developed country. However, issues like the transferability of the affordance of technology and the social effects for the viability of the innovation

need to be addressed. Building human capacity for using the innovation may be the solution for ensuring the viability of the innovation. Training has to be provided for the appropriate pedagogy and technical skills, while awareness of the benefits of the technology and the ease of use and acceptance of the technology hence influence the intention to use the technology. Strong policies would also have to be put in place for designing the instructional environment and developing the infrastructure in the developing country to ensure the success of computers in education program. In describing these issues, Malaysia is used as a case for the implementation of their computers in education program, the Smart Schools.

Nazionale delle Ricerche, Genoa, Italy

Synonyms

Digital game-based learning; Edutainment;
Game-based learning; Game-based learning environment; Learning by gaming

Introduction

This entry is focused on the use of digital games at primary school level. In particular, the entry briefly presents different modalities in which digital games can be introduced and considers, in particular, their role in stimulating and assessing students' transversal skills, that is, those cross-skills that are at the basis of the learning of many different disciplines.

Early activities in this field appear to be particularly effective, especially if we consider that thinking skills develop slowly and that primary school offers usually a more flexible context, both as far as curricula constraints and time organization, to introduce nontraditional activities. Logic and spatial reasoning skills are in particular considered making reference to research studies performed at the Istituto Tecnologie Didattiche (Institute of Educational Technology) of Consiglio Nazionale delle Ricerche the Italian National Research Council.

Games and Education

Play has always been considered an important part of children's personal and social development. Psychologists have long stressed the critical role of play in childhood development (Bjorklund and Pellegrini 2010). Today, play also encompasses the sphere of digital games. The present generation of children and youngsters has grown up with digital technology and, for many of them, digital games represent an important – if not the chief – form of play. Over the years, numerous research studies have been carried out that point to the strong potential that digital games offer for learning. At the same time, their adoption in Europe's schools has been growing steadily (Hailey et al. 2011; Boyle et al. 2015).

Educational software applications – namely those designed with the express intent of fostering knowledge acquisition through interaction with learning contents – have increasingly made use of gameful strategies and elements. Partly as a result of this, digital games have gradually found their way into primary and secondary school classrooms, where they have been shunned by some teachers

but welcomed by others (Sandford and Williamson 2006). The main obstacle to the integration of games into compulsory school curricula seems not to be the negative attitudes of teachers, schools, or parents, but rather the lack of suitable equipment and adequate teacher training and effective methodologies to integrate them in the class learning activities. A key condition for take up is the realization that the introduction of digital games must be intertwined with mainstream teaching practices and specific educational objectives; digital games must be seen as a further way of responding to the diverse range of needs that teachers have to address (Felicia 2009). They should be part, at least at primary school level, of the learning environment as well as a variety of tools and learning materials.

A wide spectrum of game types is available for learning purposes, including roleplays, adventures, puzzles, serious games, etc. (Schiffler 2006). These also feature a range of different strategies such as free exploration/navigation, question and answer routines, artifact making, etc. Some games adopted in educational contexts are explicitly designed to support the pursuit of learning outcomes (Garris et al. 2002). Others originated purely for entertainment purposes but are applied for teaching/learning (Benigno et al. 2010) or for rehabilitation (Caruso et al. 2017).

The first and most commonly highlighted potential of games is that of boosting student motivation (Connolly et al. 2007). Games offer stimulating experiences that can trigger players' intrinsic satisfaction and thus keep them motivated. Various authors (De Aguilera and Mendiz 2003; Gee 2003; Prensky 2003; Bransford et al. 2000; Caponetto et al. 2014) point to the appeal of games for motivating both young and adult players, as well as support for exploration and imagination, with opportunities for investigation, reflection, and learning (Silveira et al. 2011).

By the same token, various studies demonstrate that tangible benefits for learning need to be sought well beyond simple motivation (Whitton 2010).

In an article from the American Psychological Association (Granic et al. 2014), the authors identify four kinds of beneficial impact games can have on children: cognitive, motivational, emotional, and social. This assumption, of course, is to be further

specified considering the different typologies of games that can be used to pursue educational objectives. When referring to the use of digital games, in particular, the analysis of the efficacy for learning of their use is to be investigated in specific contexts and against clearly defined objectives and situations (Amory et al. 1999).

For example, some types of digital games are suited for fostering students' problem-solving abilities (Whitebread 1997; McFarlane 2014), for promoting creativity (Ott and Pozzi 2011), and for supporting decision-making processes in both children and adults (Charlier et al. 2011). Many authors maintain that playing digital games can have a significant impact on some children's basic cognitive abilities like, for example, reasoning and logic abilities (Bottino and Ott 2006) or computational thinking (Kafai 2006). The impact of the use of digital games on students' performance in school disciplines such as mathematics has also been investigated with positive results (Bottino et al. 2007; Freina et al. 2017b).

Considering in particular the development of basic cognitive skills, as an example, in the following reference is made to a number of research studies performed at the Institute of Educational Technologies of the Italian National Research Council which have investigated the role that digital mind games can have in stimulating and assessing primary school students' logic and spatial reasoning skills. Thinking skills and, more specifically, logic and spatial reasoning skills have been in particular considered.

Digital Games in Primary School

Addressing the role that digital play can have in primary school education requires a perspective that helps teachers see how children's digital play supports the development of crucial basic skills, such as reasoning, critical thinking, and problem-solving skills, that contemporary research identifies as necessary for supporting young children's engagement in digitized communities (Cope and Kalantzis 2009). These skills are at the basis of the learning of many different disciplines (Cotton 2001; Zohar and Dori 2003).

Early activities aimed at fostering and stimulating such skills appear to be remarkably effective, especially if we consider that thinking skills develop slowly (King and Kitchener 1994; Edwards 2013) and that primary school offers usually a more flexible context, both as far as curricula constraints and time organization, to introduce not traditional activities. This is particularly true if a game-based approach is chosen.

Different modalities can be adopted to integrate digital game playing in primary school education: use games explicitly implemented with educational purposes in mind; selecting and using, for a significant period of time, games that are not built for education (like puzzles or mind games) to foster the development of specific and clearly identified abilities; and introduce children to the building of digital games through programming. This last opportunity can be carried out both by means of a programming environment expressly developed for children or using games that allow children to act also as "builders" instead only as "player." Consider, for example, Minecraft (Ekaputra et al. 2013), a sandbox digital game where players can interact with a variety of different blocks in a 3D virtual world to create virtual houses and buildings.

The development of abilities by means of digital games (whether they are explicitly developed for this purpose or that entertainment games are used) requires to carefully identify the kind of abilities to be developed and, consequently, the types of digital games best suited for this. Consider, for example, the case of mind games that deeply require the enactment of thinking and reasoning skills (Prensky 2003). These differ from brain training games in that they usually call on the player to work out and apply problem-solving strategies so as to complete the game (Bottino et al. 2013b). Even if it is generally suggested that they can be used in schools to foster learning (Vaegs et al. 2010), they are not frequently studied from the point of view of learning outcomes (Facer et al. 2007) and few studies investigate the specific cognitive abilities they involve (Milovanovic et al. 2009). The research studies performed at the Institute of Educational Technologies highlighted the pedagogical potential of mind games to support and foster reasoning and visual spatial skills and

showed that their use under certain conditions may also have a positive impact on school performance in curricular subjects such as mathematics.

In such studies, the use of mind games to support learning is faced according to a number of different but complementary perspectives:

- Analysis of the cognitive skills involved in the use of a selected number of mind games (Bottino and Ott 2006; Bottino et al. 2012).
- Development of a methodology, based on the use of mind games, to assess the identified reasoning skills; analysis of the results obtained in applying such methodology to a sample of primary school children (Bottino et al. 2014).
- Examination of interface and game mechanics features that make mind games more or less suited for developing logic and reasoning skills (Bottino et al. 2009).
- Investigation on the effects of the appropriate use of selected mind games towards students' school performance, behavior, and attitudes (Bottino et al. 2007).
- Analysis of the impact of training spatial abilities with a number of selected digital games on mathematics performance of primary school students (Freina et al. 2017b).
- Investigation of specific characteristics of games on performing basic cognitive tasks, in particular investigation of the relationship between immersion in virtual reality, presence, and performance in spatial reasoning tasks (Freina et al. 2017a).

In order to provide some examples, two specific projects will be shortly outlined in the following.

Stimulating and Assessing Logical Reasoning and Problem-Solving Skills

The use of digital mind games to evaluate logical reasoning and problem-solving skills in primary school children was at the basis of the *Logivali* project that investigated also the most appropriate affordances that the games offer for evaluating and fostering children's solution strategies (Bottino et al. 2009). The games selected for the project involved only minimal maths or language

skills and the element of chance was marginal. Moreover, the games featured no strict time limits so that the pupils could think calmly and focus on the outcome itself rather than on how fast they managed to reach it. Feedback provided was another of the features considered in the choice of the games. Figure 1 shows screenshots of the games selected.

A test based on the use of the above-mentioned mind games was developed and tested with 26 fourth and fifth grade classes in Italian primary schools involving a total of around 500 children, who played the games individually and, at the conclusion of the game sessions, underwent the *Logivali* evaluation test. This test evaluates different abilities involved in solving the games: knowing the rules and being able to apply them in gameplay situations; being able to make an inference based on one, two, or more given piece of information or constraints posed by the game; being able to judge whether the information available at a certain point of the game makes it possible to ascertain the correctness of a given move or configuration; and being able to apply previous reasoning (at any level) in order to complete a game. In addition to the test validation activity, test results were also compared with children's school marks. This comparison revealed a general correlation between the children's school performance and their capacity to solve mind games (Bottino et al. 2013a).

Developing and Exercise Visuospatial Abilities

The "*Eyes on Me*" project was organized to support the development and consolidation of visuospatial abilities in students of the last 2 years of the Italian primary school, with the hypothesis that such a training would have a positive impact on their performance in mathematics. Twenty game-based training sessions were set up along the whole school year, involving two experimental classes, while another two classes served as control group. Students' mathematical abilities were measured at the beginning of the project and at the end using a math test that had been standardized on the Italian population.

Several game apps and computer games were accurately chosen according to their characteristics

Computers in Primary Schools, Educational Games, Fig. 1 Screenshots of the five mind games used in the *Logivali* project

in order to focus on the training of visuospatial abilities. At each meeting, students played freely, choosing between a restricted set of games focused each time on a specific ability. The games were mainly of the following types:

- Visual memory games which included activities like remembering a list of objects, the location of items on a 2D board, etc.
- Movement and rotation of 2D objects (e.g., jigsaw puzzles, tangram, etc.).
- Definition of a path on a 2D plane (e.g., maze-based games).
- Games in which an image or a solid is reflected as on a mirror (axial symmetry).
- Movement and rotation of 3D objects using games in which the player had to follow a path in a 3D structure. The interface of the games allowed to turn around the structure and to analyze it from different perspectives.

- Spatial Perspective Taking games. Spatial Perspective Taking (SPT) is the ability to predict what a scene would look like from different perspectives. In particular, the “In Your Eyes” game was used. This is a virtual reality game developed expressly for the project.

Results show a statistically significant improvement of mathematical performance in the experimental group when compared to the control one, confirming the initial hypothesis according to which having good visuospatial abilities has a positive influence on school achievements in mathematics (Freina et al. 2017b).

As far as the use of virtual reality digital games, the project also investigated if, and to what extent, immersion actually supports better performance in spatial perspective taking considering it as an embodied process (Surtees et al. 2013). To this end, the game “In Your Eyes” was developed in

three different versions, each corresponding to a different level of immersion in a virtual world: completely immersive, using Oculus rift; semi-immersive, without head-mounted display; and non-immersive. The project investigated if there is a correlation between the immersion level of the game and performance in SPT tasks. Results show that, while having the possibility to move freely in a virtual environment (immersive and semi-immersive versions) helps to have a better performance in the task, the complete immersion using a head-mounted display does not have a significant impact (Freina et al. 2017a) and can give also some drawbacks (e.g., sickness issues).

This project provide an example in which both on-the-shelf games and ad-hoc developed digital games were used with the objective to improve visuospatial abilities in primary school students.

Methodological Issues

The above briefly outlined examples and the overall experience in the field allow to sketch a possible methodology to follow, entirely or partially, when planning the introduction of digital games in primary school. Simplifying, such introduction should be designed taking into consideration the following aspects: the objectives to be pursued (e.g., the skills to be trained); the methodology to be followed (e.g., the tools available, the organization of the class work, the time allocated for each game sessions, etc.); the games to be used (selecting them considering the interface and game mechanics features of the games in relation to the objectives to be pursued); the possible effects on students' school performance, behavior, and attitudes; and students' general acceptance and enjoyment.

As far as this last aspect, from the experiences performed emerged the fact that, in general, the involvement and the interest are higher with those games that required a more active participation from the children (as it was the case, for example, for the Minecraft contest). This suggests that it would be interesting and fruitful to promote not only game playing but also their creation and development.

As the matter of fact, one can play by the rules or with the rules, in the sense of building a new game. Digital games are largely an example of playing by the rules, but games creation too can become a very valuable educational activity, able to trigger students' transversal skills, such as reasoning abilities, creative attitudes, and computational thinking (Bottino and Chiocciariello 2014). Specific environments to support games building activities are available and there is an increasing interest in their educational use. Kodu is an innovative environment for the creation of video games inspired by robot behavior programming (Coy 2013). Scratch, a visual programming environment where the instructions are assembled like LEGO building blocks (Resnick et al. 2009), is another popular environment for building digital games. Kafai and Burke (2016) argued that student-designed games teach not only programming but also academic subjects and transversal basic skills such as collaboration and team working. However, they do not suggest a shift to game making from game playing but rather argue for a more comprehensive, inclusive idea of game use in education in which both making and gaming play are considered.

Conclusions

Learning by playing is probably the ideal condition of education. The widespread diffusion of digital games and serious games makes it necessary to reflect on their educational use at all levels including primary education. Many research studies has pointed out that playing digital games it is not only enjoyable and motivating for children but can have also a significant impact on their cognitive abilities and can support the development of skills that are not specifically related to a particular disciplinary field or technical ability but which are at the basis of learning in most school subject areas.

For example, a game-based learning approach is an excellent springboard for addressing problem-solving in primary school, helping learners to reflect and reason in a systematic and structured manner. The use of mind games can help young learners acquire and/or strengthen reasoning skills that can be gainfully employed in problem-solving

strategies based on logical thinking. Games creation and coding can become too a very valuable educational activity, able to trigger students' problem-solving skills, creative attitudes, and computational thinking. Playing or making games can also deliver a clear message to learners that in order to obtain good results, they need to apply themselves with concentration and persistence.

However, the effective use of games at primary school level needs to be planned against specific and well-identified objectives and the games to be used are to be selected accordingly.

Rapid evolution in the digital games field, including development of new and attractive play modes like those based on virtual and augmented reality, is continuously broadening the range of products available. Consequently, teachers need to be informed not only about the theory, potential, characteristics, and limitations of these tools but they also need to possess the methodological capacities required to select appropriate games, and design and implement rich, well-structured learning activities featuring the use or the creation of digital games.

As experience has shown, the design of such learning activities should be done considering the demands and needs of both the class and individual learners, taking into account a number of aspects such as those that follows:

- To choose the games to work with in an effective manner by evaluating how the games fit the learning objectives that have been identified and by understanding the games mechanics and interface features (appeal, functionality, and usability) at play.
- To choose games that are relatively independent from specific prerequisites in curricular school subjects.
- To accurately tune the progression of the difficulty level.
- To appropriately calibrate the level of assistance to offer to each single student so as to trigger reasoning and strategic thinking and adequately support students' motivation and engagement.
- To consider that the use or the creation of games can prove useful if it is not sporadic

and planned on a short-term basis but if it is incorporated in activities that cover a medium/long term period of time.

The experience gained in these years in research studies involving the use of digital games supports the assumption that early and appropriately designed educational interventions involving engaging game-based activities can positively impact the development of children's cognitive basic skills and this can have an impact on students' school performance (e.g., in the areas of maths and logical reasoning) as well on students' learning attitudes and behavior.

Computers in Secondary Schools

Sigrid Schubert

Faculty Science and Technology,
University of Siegen, Siegen, Germany

Synonyms

Computer science education; Computing education; Didactics of informatics

Computers in secondary schools have a long tradition, approximately 45 years (Tatnall: [Beginnings of Computing in School Education in Australia](#)). A milestone was the presentation of Andrei Ershov “Programming, the second literacy” in 1981 at the third IFIP World Conference on Computers in Education (WCCE) (Ershov 1981). Since then experts of computer science education are discussing which programming languages are appropriate to learn and to teach this “second literacy.” There are five entries in this encyclopedia to enlarge upon this topic: programming and coding, programming languages for secondary schools, Python, Java, and Pascal.

The next step was the development of an own subject for computers in secondary schools. The subject was called “computer science” or “informatics” or “computing.” All international computer societies supported the discussion process to establish curricula for this new subject and for the related teacher education. The “Association for Computing Machinery (ACM)” started in 1993 with such a curriculum, and for a long period, the “Model Curriculum for K-12 Computer Science” of ACM published in 2006 influenced the “didactics of informatics” worldwide (ACM 2006). We summarize under “didactics of informatics” all research and teaching activities which aim to improve the learning and teaching process in the subject “computer science” or “informatics” or “computing.” There are six entries in this encyclopedia to enlarge upon this topic: Teaching about computing (computer science or other titles), Challenges of

teaching computer science, Competency model for teaching computer science, Computer science standards at schools, Curricula in computer science, and Value of teaching computer science.

Over the years an international research community emerged. At universities the teacher education of informatics required professorships of didactics of informatics. Therefore far more assistant researchers started their work in this field. In 2017 the 11th IFIP World Conference on Computers in Education (WCCE) was commenced with a doctoral consortium (IFIP-TC3 2017). The paradigm shift to a learner-centered and an outcome-oriented view on learning processes has been influenced by discussions and ongoing research in different areas of didactics of informatics. There are five entries in this encyclopedia to enlarge upon this topic: Computer science education based on fundamental ideas, Teaching methods of computing education, Informatics problem-solving, Learning from gifted peer, and Practices of computing education.

Especially as a result of the Bologna Process and the OECD Program for International Student Assessment (PISA), the development and assessment of educational standards became a high-level objective in the educational system. Standards for the major school subjects, like mathematics, natural sciences, and the first language, were developed for different levels of education. In informatics the development of educational standards is not as advanced as in those main school subjects. Nevertheless, these standards weren't based on an empirically proofed competence model for informatics.

Therefore researchers in the fields of informatics and psychology started the project MoKoM (Modelling and Measurement of Competences in Informatics) funded by the German Research Foundation (DFG) from 2008 to 2015 to develop a competence model and to measure related competences of senior class students. The research project focused on two specific domains: informatics system comprehension and object-oriented modeling. Domain-specific competence models with regard to their internal structure and different competence levels are used to define educational

standards and thereby contribute to the development of curricula, and they enable the measurement of competences and learning outcomes in diverse educational settings (Neugebauer et al. 2015).

The research project KUI (Competences for the Teaching of Informatics) cooperated partners from the universities of Munich, Paderborn, and Siegen. The project was funded by the German Federal Ministry of Education and Research (BMBF) from 2012 to 2015 to identify competencies that are particularly needed to teach informatics with the focus on three categories: subject matter competencies, pedagogical content knowledge (PCK), and non-cognitive competencies. As result a category model of the PCK competencies was developed through a content analysis of recent curricula of universities and an empirical verification by interviews of informatics teachers (Margaritis et al. 2015).

The collaborative learning with school Intranets (Schubert 2001) was another focus of didactics of informatics. There are two entries in this encyclopedia to enlarge upon this topic: "Mobile computing and mobile learning" and "Social media and networks as digital instruction and learning platforms". Didactics of informatics supported a new qualification and certification for specialist ICT teachers (Schubert 2003). There are six entries in this encyclopedia to enlarge upon this topic: Teaching with computing, Robotics, Curriculum, IT and the school curriculum, Educational games, and Applications – word processing, graphics, and spreadsheets.

We illustrate the development of didactics of informatics with some examples. Nowadays many curricula are based on empirically proved competence models of the subject. To bridge this research gap in informatics, the MoKoM project addressed the following issues:

1. Development of an empirically proved competence model
2. Development of test instruments that are appropriate for competence measurement
3. Design and evaluation of learning environments that were proved to be of high quality through competence measurement

Scenario: "You are asked by a colleague to test his software that was developed to solve configuration problems, e.g., to set up a new car or a new computer."

Question 1: "What is your strategy of testing to solve this problem? Which aspects do you have to bear in mind?"

Question 2: "Which cognitive skills are required for such a software exploration?"

Question 2.1: "Which informatics views are important for this task?"

Question 2.2: "Which complexity would you assign to this task?"

Question 3: "Which attitudes or social-communicative and cooperative skills are necessary to accomplish this?"

Question 4: "Which differences of competence levels would you expect between novices and experts?"

Question 5: "How can you as a tester be supported by this task?"

Question 6: "Could you imagine a potential pupil's procedure to solve this problem?"

Question 7: "Which obstacles would pupils have to cope with?"

Computers in Secondary Schools, Fig. 1 Scenario on testing of unknown software and its questions (Schubert and Stechert 2010)

The research process started with a theoretically derived model. In the empirical procedure, 30 experts on informatics, with a division in 3 equal groups, were interviewed (experts in the domains of didactics of informatics, computer scientists, and expert informatics teachers).

In Fig. 1 such an interview scenario is presented.

The experts answered these questions very carefully and detailed. Each interview was recorded and transcribed. The 30 transcripts could be investigated with the qualitative content analysis according to Mayring (Mayring 2003). The result was an empirically proved competence model in the area of informatics system comprehension and object-oriented modeling.

Our aim was to measure the learning results of students. Therefore, we focus on modeling of competencies as basis of test items. Two kinds of competence models are required: a structure model of competence and a model for levels of competence. The structure model of competence contains the competencies, which are required to solve problems of specific domains. We analyzed curricula of programming with PROLOG. The students are supposed to create a knowledge base referring to a given problem. The model for levels of competence contains also a differentiation into levels. At the beginning of the course,

students are supposed to add new facts and rules, which are similar to the given facts and rules. A different level would be that students are supposed to formulate own facts and rules in the following lessons. The taxonomy of Anderson and Krathwohl could be applied to separate competencies into different levels of the cognitive process (Anderson and Krathwohl 2001).

In Fig. 2, the structure models of competence are presented for learners of PROLOG, which learned already a first programming paradigm (imperative programming or object-oriented programming):

In logic programming with PROLOG, there are three different kinds of views, namely, *3.1 Knowledge base*, *3.2 Queries*, and *3.3 Tracing*. With respect to *3.1 Knowledge base*, students are supposed to understand the internal structure of logic programming. They apply, comprehend, and develop facts and rules in a knowledge base. The *3.1.1 Structure* of the knowledge base is a main theme. Furthermore, students are supposed to understand the *3.1.2 Closed-World-Assumption* in order to analyze the facts and rules. *3.1.3 Dynamic modification* of the knowledge base needs to be discussed with the students, to make them to understand the improvement of a solution and the quality of the results.

With respect to *3.2* students are supposed to perform queries. They analyze the external

 - 4.2.1 Cooperation & Teamwork
 - 4.2.2 Empathy: Change of Perspectives & Roles (User, Developer)
 - 4.3 Motivational and Volitional Skills
 - 4.3.1 Openness to new Ideas and new Requirements

Computers in Secondary Schools, Fig. 2 Structure model of competencies of logic programming

Your parents want to publish their best recipes in an online cookbook. They want to demonstrate the preparation of the food through videos. Your parents also have purchased a new software for editing the videos. Unfortunately, they do not know the software very well because they previously used another program, which was especially designed for beginners. But they know that the new software uses the same open-source components to de- and encode videos as the old software. According to this, which of the following statements are true?

1. Both of the programs own the option “Distort Video” that can be found under the menu point “Effects.”
2. Both of the programs can import audio files in different formats.
3. Both of the programs can import videos in the same format for editing.
4. Both of the programs can enhance the videos with effects.
5. Both of the programs support different view modes for windows.
6. Both of the programs can export videos in the same resolution.
7. Both of the programs are suitable for beginners.

Computers in Secondary Schools, Fig. 3 Task of informatics system comprehension

structure of logic programming. Students formulate queries to solve a given problem, and they should be able to predict the answer of the system. 3.1.2 *Closed-world assumption* has a strong connection with this competence.

3.3 *Tracing* combines the understanding of the internal and the external view. Students are supposed to understand 3.3.1 *Unification and backtracking*, especially intern and extern backtracking, 3.3.2 *Trace modus*, 3.3.3 *Box model*, and 3.3.4 *Parse tree* can be used to illustrate and to explore the structures and to support the competence 2.2.3 *Development of logic programs including debugging*.

The next step in didactics of informatics would be the design of tasks for students. In Fig. 3 such a task of informatics system comprehension is presented:

We created 18 tasks (test items) and tested them with 800 computer science students in German upper secondary schools (Magenheim and Schubert: [Competency Models in Computing Education](#)). The measurement instrument is now available for all teachers and researchers in the field of didactics of informatics. It covers only one part of computer science education, for all the other interesting topics (Romagosa I Carrasquer:

[Snap! Programming System](#)) are also competency models required. The examples given may encourage our worldwide research community to establish such basics for teaching and learning about computers in secondary schools.

Introduction

This entry introduces educational games in secondary schools. Educational games include three main types of educational activities with a

playful learning intention supported by digital technologies: educational serious games, educational gamification, and learning through game creation. Educational serious games are digital games that support learning objectives. Gamification is defined as the use of “game design elements and game thinking in a non-gaming context” (Deterding et al. 2011, p. 13). Educational gamification is not developed through a digital game but includes game elements for supporting the learning objectives. Learning through game creation is focused on the process of designing and creating a prototype of a game to support a learning process related to the game creation process or the knowledge mobilized through the game creation process. Four modalities of educational games in secondary education are introduced in this entry to describe educational games in secondary education: educational purpose of entertainment games, serious games, gamification, and game design.

Digital Games Among Secondary Learners

Play is renowned as an essential activity for the development of a child from the youngest age; but parents and educators raise important concerns about the negative effects of digital games on secondary learners. Among these concerns, the addictive behavior in relation to massively multiplayer online role-playing game (MMORPG) is among the worst expected outcomes when adults explain their worries about digital games (Gentile 2009). Some studies have pointed that use of digital games could be a symptom of depression among young adults (Thomée et al. 2012). Using games as a way to escape or due to social pressure is also leading to higher levels of addictive uses of games; however, among the factors which do not seem to be linked with the use of games is the parental control (Giles and Price 2008). While the general conception of digital games is based on entertainment, teenagers and young adults also have expectations about the use of gender affects in the pedagogical expectations on digital game-based learning (DGBL), which differs according to their gender; Karakus et al. (2008, p. 2522)

observe that “female students expect games to have instructive elements, while males desire elements that are entertaining, competitive, and multi-player.” In digital games, male player shows higher skills and time spent in secondary education (Dindar 2018) and high school (Chou and Tsai 2007). The representation of age and gender differences in the use of (serious) games leads to stereotypes that are overcome by recent studies on the diversity of playing activity across genders and ages (Loos and Zonneveld 2016).

Educational Serious Games (ESG) in Secondary Schools

Playing is often perceived as a hobby or an unproductive waste of time (Mackereth and Anderson 2000). In the last few years, authors, editors, and researchers in game-based learning (GBL) have adopted the term serious game to pinpoint the serious nature that a game can have in the development of learning, health, or other “serious” objectives considered by adults as profitable. Serious games permit to develop playful learning situations related to disciplinary areas and to twenty-first-century skills such as collaboration, problem-solving, and creativity (Connolly et al. 2012). Among serious games, those having learning objectives could be named under the name of educational serious games (ESG). In secondary education, ESG are developed within the different disciplines of the curriculum such as mathematics (Ke 2013), science and technology (Barma and Daniel 2017; Hodges et al. 2018), history, and language learning (Patino et al. 2016). History serious games such *Frequency 1550* (Huizenga et al. 2009) possess a game universe allowing to engage the learners in Amsterdam at 1550. Other popular digital games in secondary schools such *Classcraft* are based on popular entertainment games (Sanchez et al. 2017).

Digital Game-Based Learning in Secondary Education

Within the educational games, this section introduces digital game-based learning (DGBL),

serious games, and educational gamification in secondary schools including four types of activities:

1. *Educational purpose or “modding” of entertainment games.* The pedagogical use of digital games that were not specifically conceived for learning or for the pedagogical use of games without educational intentions, for example, the use of *Minecraft* to work on social sciences (citizenship) or mathematical concepts (Hill 2015; Isiksal and Askar 2005).
2. *Educational serious games.* The pedagogical use of educational serious games (ESG) conceived with a “serious” educational goal, such the mobile city game called *Frequency 1550*, developed to help secondary education learners to develop historical knowledge of medieval Amsterdam (Huizenga et al. 2009). Within the last years, the use of augmented reality (AR) and virtual reality (VR) in educational serious games in the field of science and technology has allowed to approach abstract concepts in a dynamic way through games specifically developed for learning concepts such as electromagnetism (Barma and Daniel 2017) or chemistry (Hodges et al. 2018) in secondary education. Some ESG are based on simulations, defined as “analogies of a real-world situation” (Prensky 2001, p. 128), in which the learner has the possibility to play with a model or microworld in order to better understand a system.
3. *Educational gamification.* Educational gamification engages game mechanics in an educational context, such in the field of science education (Su and Cheng 2015). In some contexts, “framing an activity as a game” has induced the learner to a similar engagement and psychological relation to the activity as using game mechanics (Lieberoth 2015). In terms of learning performance, gamification has showed mixed results (Seaborn and Fels 2015), specially when the gamification is based in game elements such as scores and leaderboards (Toda et al. 2017).
4. *Game design and creation.* In this case, the interest resides in the interdisciplinary design

procedure of a game. Creating a game is considered as a knowledge modeling activity, which can engage in secondary level learners in same-age or intergenerational game design activities (Cucinelli et al. 2018).

Conclusion

Learning through gaming is not limited to children, and secondary education has been integrating educational serious games (EGS), repurposed entertainment games, gamification systems, and game design and creation activities within the last years. While results point to certain benefits in terms of performance in certain tasks, the most important aspect is the learners' engagement and the playful intention which is shared within these different initiatives. Research studies in the next years should continue to study the impact and effects of EGS, repurposed entertainment games, gamification systems, and game design and creation activities taking into account not only the specific game components such the Learning Mechanics and Game Mechanics (Arnab et al. 2015; Proulx et al. 2016) but also the state-of-the-art frameworks and methodologies within the different disciplines concerned by DGBL studies: from the learning sciences and psychology (Boyle et al. 2016), computer sciences and human-computer interaction (Romero et al. 2012), narrative and storytelling (Boyle et al. 2014), and other disciplinary and cross-disciplinary studies. The development of empirical studies including learning analytics adapted to DGBL leads to the emergence of the playing analytics (Sanchez and Mandran 2017), which can contribute to better understand the learning process within the game-based learning activities developed in digital environments. Through the playing analytics, data could be used to develop adaptive systems embracing the potential of machine learning for education in the next generation of educational games for secondary education but also in other educational levels.

Computing Curricular Report CE2016, A Summary

John Impagliazzo
School of Engineering and Applied Science,
Hofstra University, Hempstead, NY, USA

Synonyms

Computer education; Computer engineering;
Computing education; Engineering education

Overview

The report titled, *Curriculum Guidelines for Undergraduate Degree Programs in Computer Engineering (CE2016)* (Impagliazzo et al. 2016), better known as CE2016, was an endeavor conducted by the Association for Computing

Machinery (ACM) and the IEEE Computer Society. This article is largely based on a culminating paper for the project (Nelson et al. 2017) that reflects an integration of material from earlier workshops and presentations; it also summarizes the content that led to the ACM publication of the CE2016 report in December of 2016. CE2016 is part of a series of reports covering curricula for a variety of computing fields. This article discusses significant aspects of CE2016 and the ways institutions might use the report to update or create computer engineering programs.

The computer engineering field has witnessed rapid advances over the past decade and the field expects to continue to advance even more rapidly. To help in the design of forward-looking curricula to prepare graduates of computer engineering programs for practice, the CE2016 report draws upon an earlier report titled, *Computer Engineering 2004: Curriculum Guidelines for Undergraduate Degree Programs in Computer Engineering*, also known as CE2004 (Soldan et al. 2004). This 2004 report also draws upon recent efforts in computing curricula developed by the ACM, IEEE, and the Association for Information Systems (AIS). These efforts resulted in published curricula recommendations in computer science (CS2013), information systems (IS2010), information technology (IT2017), and software engineering (SE2014). These reports are available online at the ACM website (ACM curricular website).

CE2004 set out the technical, communication, and professional competencies important at the time. It discussed the state of the field, and the role of the laboratory, engineering tools, teamwork, and lifelong learning in a computer engineer's education. Many computer engineering programs today reflect the content of this work. To keep up with rapid advances in computer engineering, the societies convened a review taskforce in 2011 to consider whether and how to update CE2004. That taskforce surveyed society members interested in computer engineering and received hundreds of responses. This input identified some new and emerging areas that the community believed should be part of a modern computer engineering graduate's knowledge. These include information security, parallel

processes and algorithms, concurrent hardware and software design, mobile embedded systems, and power-aware software engineering. Guided by this initial input, a steering committee of 11 members incorporated this information into draft revisions of the guidelines, which committee members presented, debated, and refined at many presentations and workshops worldwide. A key contribution of CE2016 is to ensure that the intellectual framework for the discipline remains current with evolving professional practice.

The purpose of the CE2016 report is to provide guidance to programs and present accumulated knowledge for their consideration as they seek to improve continually. The report seeks to help new programs as they invent or re-invent themselves and to supplement the vision of educational institutions, industry, and various accrediting bodies in supporting innovation and quality in academic programs. University faculty can use the CE2016 guidelines to design new programs or to see how their programs align with the expert consensus view of the field and then consider whether updates would better serve their constituents. Employers can use the report to gain insight at the abilities newly graduated computer engineers might possess. Potential students might use them to see how the field aligns with their interests.

The Discipline of Computer Engineering

To provide a context for curricular design, CE2016 defines computer engineering as a discipline, discusses how the field has evolved, and discusses characteristics of computer engineering graduates. CE2016 distinguishes computer engineering from computer science, electrical engineering, software engineering, and other disciplines. As an academic field, computer engineering encompasses the broad areas of electrical or electronics engineering and computer science. CE2016 defines this discipline as follows.

Computer engineering is a discipline that embodies the science and technology of design, construction, implementation, and maintenance of software and hardware components of modern computing systems and computer-controlled equipment.

This unique combination prepares students for careers that deal with computer systems from their design through their implementation. Computing systems are components of a wide range of products such as fuel injection systems in vehicles, medical devices such as X-ray machines, communication devices such as smart phones, and household devices such as alarm systems and washing machines. Designing computing systems and computing components for products, developing and testing their prototypes, and implementing them to market are examples of what computer engineers typically do.

The CE2016 report describes the expected background, knowledge, and skills employers expect to see from graduates of computer engineering programs. These include the ability to design computer systems, the realization of the importance of practicing as professionals, and having the breadth and depth of knowledge expected of a practicing engineer. It also discusses ways in which programs in computer engineering may have to stand up to the scrutiny of validation and accreditation by government or private agencies.

CE Body of Knowledge

The foundation for CE2016 is a fundamental body of knowledge from which an institution could develop or modify a curriculum to fit its needs. This body of knowledge (BoK) contains broad knowledge areas that are applicable to all computer engineering programs worldwide. Changes within this rapidly changing field since the previous report and projections for the next decade prompted significant revisions to the BoK for CE2016.

The BoK has a three-level hierarchical structure. The highest level is the *knowledge area* (KA), which represents a disciplinary subfield of computer engineering. The 12 knowledge areas of CE2016, listed in Table 1, each contain an *area scope* that describes its context. Each area then contains smaller divisions called *knowledge units* (KUs), which represent individual themes within an area. To capture the sense of what students

Computing Curricular Report CE2016, A Summary, Table 1 CE2016 knowledge areas

Tag	Knowledge area	Core hours
CE-CAE	Circuits and electronics	50

CE-SEC	Information security	20
CE-SGP	Signal processing	30
CE-SPE	Systems and project engineering	35
CE-SRM	Systems resource management	20
CE-SWD	Software design	45
	Total	420

should learn in connection with each knowledge unit, CE2016 uses *learning outcomes* to describe each knowledge unit. The emphasis on *learning* is important. Taxonomies of verbs such as “define” or “evaluate” are useful to describe the expected depth of learning. Levels of learning range from basic abilities, such as reciting definitions, to advanced abilities, such as engaging in synthesis and evaluation. The verbs used to describe learning outcomes in KUs reflect those mentioned in Bloom’s taxonomy (Bloom 1956). Hence, *learning outcomes* provide a mechanism for describing not just knowledge and relevant practical skills but also personal and transferable skills. They describe what we expect a student to know or be able to do by the time of graduation. We can infer the minimal desired depth of coverage associated with each knowledge unit from the language used to express the learning outcomes.

One of the goals in creating CE2016 was to keep the required component of the BoK as small as possible. This allows computer engineering programs to be as flexible as possible since program goals or objectives vary widely from program to program. To implement this principle, the report distinguishes among the KUs by identifying those that are *core* or essential units to the

curriculum compared to those that are *supplementary*. Core components comprise knowledge and skills for which there is broad consensus that anyone obtaining a 4-year degree in the field should acquire. Supplementary components comprise knowledge and skills that reflect expectations for advanced work according to the needs of a program. Table 2 shows the knowledge area for embedded systems with its related knowledge units. KUs CE-ESY-1 to CE-ESY-12 are core units; CE-ESY-13 is supplementary.

To give readers a sense of the time required to cover a knowledge unit, CE2016 expresses time in hours, specifically in *core hours*. Core hours are suggested time of initial exposure to new material and do not assume any delivery method (traditional lecture, video lecture supporting a flipped classroom, directed study, seminar, etc.). As shown in Table 1, the core hours of the BoK total 420, which is the equivalent of one academic year, leaving ample time for additional coverage of core and elective KUs, math and science, and

general studies. Thus, a program may tailor the curriculum to meet its own unique objectives.

In working with the CE2016 guidelines, it is important to realize that the core components refer to the knowledge and skills all students in all computer engineering degree programs *should* attain. Additionally, the knowledge areas are *not* courses, and the core components do *not* constitute a complete curriculum; each program may choose to cover the core knowledge units in a variety of ways. Supporting mathematics, science and general studies are necessary to produce a competent computer engineer. Furthermore, it is not the case that a program should achieve core knowledge units only within a set of introductory courses early in the 4-year curriculum: while some core knowledge units are introductory, a program can address some core KUs only after students have developed significant background in their studies.

Beyond the computing knowledge areas, CE2016 recommends that a robust computer engineering program have at least four areas of capability that require at least 120 hours in mathematics to produce a competent computer engineering professional for the 2020s, although programs typically include much more mathematics to achieve their goals. The four areas, for which core knowledge units appear in the report, include analysis of continuous functions (calculus), discrete structures, linear algebra, and probability and statistics. These emphasize what the steering committee considers essential to computer engineering.

Computing Curricular Report CE2016, A Summary, Table 2 Embedded systems KA with its related KUs

CE-ESY	Embedded systems [40 core hours]
CE-ESY-1	History and overview [1]
CE-ESY-2	Relevant tools, standards, and/or engineering constraints [2]
CE-ESY-3	Characteristics of embedded systems [2]
CE-ESY-4	Basic software techniques for embedded applications [3]
CE-ESY-5	Parallel input and output [3]
CE-ESY-6	Asynchronous and synchronous serial communication [6]
CE-ESY-7	Periodic interrupts, waveform generation, time measurement [3]
CE-ESY-8	Data acquisition, control, sensors, actuators [4]
CE-ESY-9	Implementation strategies for complex embedded systems [7]
CE-ESY-10	Techniques for low-power operation [3]
CE-ESY-11	Mobile and networked embedded systems [3]
CE-ESY-12	Advanced input/output issues [3]
CE-ESY-13	Computing platforms for embedded systems

CE Curricula

By its very nature, a computer engineering program should reflect an engineering ethos that permeates all years of the curriculum in a consistent manner. Such an approach has the effect of introducing students to engineering (particularly computer engineering), teaching them to think and function as engineers, and setting expectations for the future. Preparation for practice is essential because most graduates from 4-year programs directly begin professional practice in much of

the world. Therefore, CE2016 goes beyond defining the body of knowledge to discuss integration into the curriculum of engineering design, laboratory experience, problem-solving, and critical thinking skills, as well as providing the background to adapt to new and emerging technologies in an agile manner. In addition, personal (soft) skills, oral and written communication skills, teamwork, lifelong learning skills, and professionalism are fundamental to preparation for professional practice of computer engineering.

Design must pervade the entire computer engineering curriculum, with students encountering different approaches to design so that they become familiar with the strengths and weaknesses of these approaches. The concept of a culminating design project is a widely valued important experience occurring toward the end of a curriculum. Students consider a significant problem associated with a discipline and, in solving the problem, they demonstrate their ability to apply methodically engineering principles to generate a solution. For computer engineering, the solution typically involves the design and implementation of a system or subsystem containing both hardware and software components and considering a variety of interactions and tradeoffs.

Laboratory experiences are likewise an essential part of the curriculum. It is important that computer engineering students have many opportunities to observe, explore, and manipulate characteristics and behaviors of actual devices, systems, and processes. This includes designing, implementing, testing, and documenting hardware and software, designing experiments to acquire data, analyzing and interpreting that data, and using that data to correct or improve the design and to verify it meets specifications. To support such experiences, CE2016 includes an appendix that describes possible laboratory configurations useful for developing modern student laboratory experiences for computer engineering programs.

Since computer engineering is a profession, CE2016 also addresses incorporation of professional issues throughout the curriculum. It is important that the curriculum include a wide range of professional practice issues, including

consideration of the social context in which graduates implement engineering designs, legal and ethical issues and codes, and professionalism in the workplace.

Curricula Implementation

To illustrate how to apply the guidelines of CE2016 within different institutional contexts, the report provides several sample curricula implementations for computer engineering programs as appendices. To provide a framework for a curriculum that illustrates the ideas presented in the report, the first three examples assume that each year consists of two semesters with a student studying four to five modules (courses) per semester, and students should experience at least two computer engineering modules in the 1st year of study, at least four modules in the 2nd year of study, and at least five modules in each of the 3rd and 4th years of study. Many institutions in the United States use the above pattern; the same is true in many other parts of the world. The fourth example of a curriculum implementation represents a typical 4-year program in China. The remaining example shows possible curricula reflecting those compatible with the Bologna Declaration in Europe.

All sample curricula in the appendix of the report use a common format with five components. They include (a) a set of educational objectives for the program of study and an explanation of any assumed institutional, college, department, or resource constraints; (b) a summary of degree requirements, in tabular form, to indicate the curricular content in its entirety; (c) a sample schedule that a typical student might follow; (d) a map showing coverage of the computer engineering body of knowledge by courses in the curriculum; and (e) a set of course descriptions for those courses in the computing component of the curriculum.

Appendix A of this article presents a sample 4-year computer engineering curriculum model that an electrical and computer engineering (ECE) department might administer. Appendices in the CE2016 report also demonstrate how the core knowledge units of the CE2016 BoK map to the 12 BoK

Appendix A

Course	Description	Credit	Course	Description	Credit

		14			14

knowledge areas to required course in the curriculum. The report also provides a short description of each course used with the sample curriculum.

Conclusion

The CE2016 guidelines support the design of computer engineering curricula that will prepare graduates to function at entry-level positions in industry for continued career growth or to enter graduate programs for advanced study. The recommendations reflect input from industrial and educational institutions. This report is the result of a cooperative global effort of the professionals involved. Its intent is to provide interested parties

and educational institutions worldwide a flexible way to implement a strong program in computer engineering. The CE2016 steering committee trusts that it has achieved that goal.

Computing Curricular Report IT2017, A Summary

Hala Alrumaih
Al Imam Mohammad Ibn Saud Islamic
University, Riyadh, Saudi Arabia

Introduction

Over the years, the Association for Computing Machinery (ACM) has directed many efforts to create a series of curricular documents that are ongoing even today. In 2008, ACM and the IEEE Computer Society (IEEE-CS) published the first curricular report for information technology (IT), called IT2008 (Lunt et al. 2008). Since that time, many new technologies emerged and

flourished. In 2012–2013, ACM formed an exploratory committee to decide whether IT2008 required updating. After an affirmative response, ACM formed a task group charged with developing an update of IT2008 that was appropriately forward looking to prepare graduates for the mid-2020s. The report is the 2017 document titled, “Information Technology Curricula 2017: Guidelines for Baccalaureate Degree Programs in Information Technology,” known also as IT2017 report (Sabin et al. 2017a). This chapter provides a summary of the IT2017 report and the IT curricular framework. Developing such guidelines for high quality, rigorous IT degree programs benefits from a comprehensive approach that engages international perspectives and reflects needs and expectations from industry and IT professional societies (Sabin et al. 2015a, 2016a). The IT2017 report is the second edition of the ACM/IEEE-CS Curriculum Guidelines for Baccalaureate Programs in Information Technology; it includes technology and educational advances that occurred since 2008 (Sabin et al. 2015b).

IT2017 Task Group

The IT2017 task group is the committee that developed these guidelines. Its membership consists of 12 professionals, five of whom form the task group’s executive committee. These 12 professionals represent academia (nine) and industry (three). The task group membership encompasses three continents (Asia, Europe, and North America) and five countries (Canada, China, the Netherlands, Saudi Arabia, and the United States). The group members represent many international societies, including ACM, IEEE-CS, two ACM special interest groups (IT Education and Computer-Human Interaction), and other organizations.

The IT2017 task group has worked diligently to make revisions and produce an appropriately forward-looking document that is globally relevant and balances perspectives from educators, practitioners, and IT professionals. The IT2017 task group holds the view that IT programs should prepare students with knowledge and skills in learning contexts that emphasize development of competencies: what students do and how they

demonstrate performance with what they know. The main goal of the task group is to produce a curricular framework and guidelines for world-wide baccalaureate IT degree programs that prepare graduates professionally for current and new technologies for the next decade. To accomplish this goal, the task group has incorporated the results of previous curricular reports as a backdrop for its activities. These include reports on computer engineering, computer science, information systems, and software engineering. In addition, the group decided to conduct many faculty and industry surveys to ascertain multinational indicators, predictors, and sources surrounding information technology as an academic discipline and industry sector.

Vision and Mission

The IT2017 task group has adopted both a vision and a mission for the project. Its vision is “The IT2017 report will become a sought-after and durable set of guidelines for use by educational institutions around the world to help them develop IT curricula for the next ten years!” Knowledge alone is not sufficient to be productive in the changing information technology world. IT competencies require skills and dispositions that complement knowledge to achieve professional expectations of a modern workplace. Therefore, the mission of the IT2017 project is “To produce a globally accepted document of information technology competencies appropriate for baccalaureate degree programs that meets the growing demands of the changing technological world and that is useful for both industry and academia.”

Public Comment

The report contains feedback that the task group received from public comment and review solicited for report versions in January of 2015, August of 2016, and May of 2017. Some task group members participated in two international working groups (Sabin et al. 2015b, 2016a) to lead extensive data gathering and analysis efforts

and to garner input from academia and industry through surveys conducted in 2015 (almost 700 responses, 597 computing faculty and 91 industry respondents) and in 2016 (over 350 responses from Latin America, 182 faculty and 177 employers). Report development dissemination included a variety of venues to engage educational and professional communities worldwide: curriculum design workshop and panel at IEEE EDUCON in Tallinn, Estonia in 2015 (Impagliazzo 2015) and Abu Dhabi in 2016 (Impagliazzo et al. 2016a), and a panel in the first National Computing Colleges Conference in Saudi Arabia in 2016. Other panel sessions on the report status updates occurred at SIGITE conferences in Chicago in 2015, Boston in 2016 (Sabin et al. 2016b), and Rochester 2017 (Sabin et al. 2017b), at the Western Canadian Conference on Computing Education (WCCE’16) in British Columbia, Canada (Byers et al. 2016), and at ITiCSE’16 in Arequipa, Peru (Impagliazzo et al. 2016b).

Definition of the Information Technology Academic Discipline

Worldwide, the term “information technology” generally refers to all aspects of computing and its integration into all aspects of today’s society and digital platform economy. Organizations of every kind are dependent on information technology and computing systems that must work properly and efficiently, be secure, and scale with organizational objectives and customer needs. IT professionals select computing products and services, integrate them to enhance supported environments, and develop, adapt, and manage computing technologies to meet the organization’s goals and business objectives. The IT innovations are the object of study of the information technology discipline. These innovations frame the questions IT professionals and researchers pose and inform the methods and practices by which IT complex problems are solved and new discoveries are made. IT2017 report proposes the following definition of the information technology discipline:

Information Technology is the study of systemic approaches to select, develop, apply, integrate, and administer secure computing technologies to enable users to accomplish their personal, organizational, and societal goals.

IT2017 Curricular Framework

The IT2017 report suggests a learner-centered framework for programs that prepare successful IT graduates for professional careers or further academic study. Inspired by the IT competency model for an associate degree curriculum (Hawthorne et al. 2014) and receptive to industry demands for competent and competitive IT workforce, the IT2017 report has adopted a full competency-based approach to learning IT. The approach is somewhat unique among the ACM/IEEE curricular reports. The report articulates competencies grounded in content of essential and supplemental IT domains. It enables faculty members to implement IT programs that articulate convincingly what student should be able to achieve by the time of graduation.

The IT2008 report’s depiction of the IT discipline’s key curricular components represented five pillars (programming, networking, human-computer interaction, databases, and web systems) built on a foundation of IT fundamentals and overarched by information assurance and security as well as professionalism. For the current situation, the IT2017 framework depiction is an interwoven tapestry of interrelated studies and activities. Another innovative change is the elimination of hours as a measure of domain coverage. A competent graduate from an IT degree program should experience the equivalent of at least 1.5 years of information technology studies. The report provides guidance so IT graduates can perform competitively in the marketplace.

It is possible to consider that a report of this type is much too complex with framework domains and associated competencies. In today’s computing educational environments, it is simply not possible to list only a set of courses with their lists of topics. IT programs vary among institutions. Furthermore, the technological field changes rapidly and what seems important today

may just be a passing fancy. Thus, it is important to prepare students for this undetermined future by establishing foundational competencies coupled with the flexibility to adapt to new situations that await them after graduation.

Structure of the IT2017 Curricular Framework

One of the goals in this IT2017 report is to keep the implementation requirements of the IT curricular framework as few as possible to allow flexibility for programs in information technology. To implement this principle, a distinction among the IT domains occurs by identifying those that are essential to an IT curriculum compared to those that are supplemental. Essential domains encompass competencies that anyone obtaining an IT degree must acquire. Supplemental domains encompass competencies in domains where students do more specialized work according to the goals of a program. Supplemental domains provide IT programs more directed choices, flexibility, and the opportunity to include new domains that could emerge in the future. All degree programs should require students to achieve competencies in some subset of the supplemental domains. Table 1 shows the IT domains as presented in the report together with their essential or supplemental classifications and 19 distinct colors associated with each domain. Note that some domains cross both essential and supplemental classifications. The table also shows the percent associated with each domain relative to the entire IT curriculum in a baccalaureate IT degree program.

The IT2017 task group has recommended that the breakdown of an IT curriculum in a baccalaureate degree program consists of approximately 40% from the essential IT domains, approximately 20% from the supplemental IT domains, and the remaining 40% representing IT electives. A summary of the IT curricular framework appears in two tables in the report; one table for the essential IT domains and the other for the supplemental IT domains. The tables show the IT domains, their subdomains, and the level of learning engagement for each subdomain

Computing Curricular Report IT2017, A Summary, Table 1 Competency domains of the IT curricular framework

IT Domains	Essential Percent	Supplemental Percent
Essential Only (5)		
Information Management (IMA)	6%	0
Integrated Systems Technology (IST)	3%	0
Platform Technologies (PFT)	1%	0
System Paradigms (SPA)	6%	0
User Experience Design (UXD)	3%	0
<i>Subtotal:</i>	19%	0
Essential + Supplemental (5+5)		
Cybersecurity Principles (CSP) / Cybersecurity Emerging Challenges (CEC)	6%	4%
Global Professional Practice (GPP) / Social Responsibility (SRE)	3%	2%
Networking (NET) / Applied Networks (ANE)	5%	4%
Software Fundamentals (SWF) / Software Development and Management (SDM)	4%	2%
Web and Mobile Systems (WMS) / Mobile Applications (MAP)	3%	3%
<i>Subtotal:</i>	21%	
Supplemental Only (4)		
Cloud Computing (CCO)	0	4%
Data Scalability and Analytics (DSA)	0	4%
Internet of Things (IOT)	0	4%
Virtual Systems and Services (VSS)	0	4%
<i>Subtotal:</i>	0	
IT2017 TOTAL Essential Domain Competencies:	40%	

expressed by level indicator shown in brackets. Tags differentiate the different domains and subdomains.

Assume an IT program consists of 120 credits (semester hours) over 4 years. Then at least 1.5 years of study consists of at least 45 credits or 37.5% of the program. The mathematics curriculum should be at least 12 credits (10%) and the science curriculum should be at least 6 credits (5%) as recommended by the task group. Figure 1 illustrates the curriculum requirements for an baccalaureate IT program. Note that the other curricula in the program (47.5%) could consist of any combination of IT and non-IT subjects reflective of the mission and needs of the program.

IT Domain Clusters

A competency-based IT curricular framework considers the long-term goal of learning to achieve genuine competence through ongoing transfer that spans what students learn through college and graduates develop in their profession. By using a competency-based approach, IT faculty members who implement, evaluate, or update their IT programs need to rethink the IT domains through the lens of performance goals and how students demonstrate what they can do with what they have learned.

To guide departments and faculty members through a competency-based curriculum

Computing Curricular Report IT2017, A Summary, Fig. 1 Example of a curriculum for an IT program of 120 credits, with IT, mathematics, and science curricular requirements

development process, the report uses IT domain clusters to describe the IT curricular framework’s domains. The purpose of an IT domain cluster is to connect directly the scope of the domain with competencies that students achieve within a domain with a more refined characterization of domain content through subdomain information. Table 2 offers an example of IT domain cluster for the Software Development and Management essential domain.

IT Competencies

Generally, the term competence refers to the performance standards associated with a profession or membership to a licensing organization. Assessing some level of performance in the workplace is frequently used as a competence measure; that is, measuring aspects of the job at which a person is competent.

There is general agreement in education that success in college and career readiness requires

Computing Curricular Report IT2017, A Summary, Table 2 Example of IT domain cluster

Essential competency domain: software development and management	
Scope	
1. Software process models and software project management	
2. Software development phases: requirements and analysis, design and construction, testing, deployment, operations, and maintenance	
3. Modern software development and management platforms, tools, and services	
Competencies	
A. Use tools and services to develop computing systems that consider platform constraints, supports version control, tracks requirements and bugs, and automates building (<i>Development</i>)	
B. Use project management tools and metrics to plan, monitor, track progress, and handle risks that affect decisions in a computing systems development process involving a diverse team of talents and professional experiences (<i>Management</i>)	
Subdomains	
Process models and activities	Management
Platform-based development	Deployment, operations, and maintenance
Tools and services	

that students develop a range of qualities, typically organized along three dimensions: knowledge, skills, and dispositions. The IT2017 report has adopted a working definition of *competency* that connects these dimensions, namely:

Competency = Knowledge + Skills

+ Dispositions

The working definition of competency in the IT2017 report avoids perpetuating the practice of preponderantly using the knowledge lens and centering curriculum guidelines primarily on a body of knowledge of IT. The task group note that recent ACM computing curricula reports for IT associates degree programs and graduate programs in information systems have also adopted a competency model approach (Hawthorne et al. 2014).

The basis for constructing a curriculum that is competency-driven is to align learning outcomes, activities, and assessments. On a practical,

Computing Curricular Report IT2017, A Summary, Fig. 2 IT competency model

operational level, the IT2017 task group conceptualized competencies as higher-level learning outcomes linked to performance tasks and descriptive of the professional context of those tasks. The task group follows Van der Klink and Boon advice that the “fuzziness” of competencies “disappears in the clarity of learning outcomes.” A sensible method to articulate competencies is to select learning outcomes along with evaluation indicators suggestive of a professional context. A performance perspective on learning is not possible without performance-based assessments. The design of performance assessments considers authentic situations and aspects of work that professionals encounter and through which they demonstrate expertise. Thus, a promising practice to implement a competency-based curriculum is to identify and link the curriculum to professional contexts. The task group’s operational definition of IT competencies connects knowledge, skills, and dispositions in a professional context as shown in Figure 2.

Contemporary Illustration of IT

Recall that the essential domains form the core of an IT curriculum. The supplemental domains provide

texture with enhancements and embellishments to reflect the local needs of a program’s mission and constituents. That is, a modern image should depict the essential and the supplemental meanings of a curriculum carefully woven together into a tapestry of relevance and utility for the IT field.

Figure 3 illustrates a tapestry as a modern version of information technology. For this illustration, the weft threads (vertical) of the tapestry go through the warp threads (horizontal). In this case, the ten warps represent the ten essential domains of the IT curricular framework; the nine wefts represent the nine supplemental domains of the framework. Note that one warp thread (ITE-CSP) permeates both warp and weft roles in the image, which emphasizes that cybersecurity is a contemporary “thread” woven throughout the tapestry – and hence, the field of information technology. This woven warp thread may change name over time as IT evolves. The resulting image provides a pictorial illustration showing the way IT weaves the breadth of computing.

New technologies keep emerging thereby amplifying the integration of IT competencies. Figure 3 attempts to capture the spirit of future IT innovations by allowing the warp threads and the weft threads to weave the tapestry of a dynamic and relentlessly evolving IT field.

Computing Curricular Report IT2017, A Summary, Fig. 3 Modern illustration depicting the field of IT. (Courtesy of Richard Fry)

Content of the IT2017 Report

The IT2017 report addresses baccalaureate degree programs in information technology. The main body of the report consists of eight chapters. Chapter 1 introduces the report. Chapter 2 discusses the role of IT among other computing disciplines and proposes a new definition for the information technology discipline. It also describes competencies that students develop through their program of study and should demonstrate upon graduation. Chapter 3 highlights the importance of professionalism in the practice of information technology. Chapter 4 discusses the meaning of competencies and proposes an operational definition for information technology competencies. Chapter 5 discusses an industry perspective toward information technology. It includes current data and graphs related to IT competencies from IT employers' viewpoint.

Chapter 6 presents an overview of the IT curricular framework and describes a basis for curricular recommendations. The vision, mission, goals, underlying principles, perspectives from industry, and professional practice inform this framework. The chapter also articulates various IT competency domains of the curricular framework, the percent of time devoted to an IT curriculum in a degree program, mathematics and science curricular requirements, and various competencies an individual need to become an effective professional in information technology.

Chapter 7 provides a discussion on transforming competencies into a curriculum; it also discusses issues affecting the implementation of an IT curriculum such as the arrangement of a student's program of study, inclusion of courses within the major and those in other areas of the educational experience as well as other implementation considerations. Chapter 8 discusses some

challenges that may arise when creating or continuing IT programs such as curriculum design, computing resources, and faculty issues.

The bulk of the material in the report appears as five appendices. Appendix A presents part of the first chapter in the Enterprise Information Technology Body of Knowledge (EITBOK) report currently under development by the IEEE Computer Society. Appendix B gives examples of IT performances related to various IT domains and their subdomains. These performances may be useful for developing learning outcomes for a given IT course or possible questions to assess student performance. Appendix C illustrates typical sample curricula that might appear at different academic institutions together with related mappings of the framework and course descriptions. Appendix D provides samples of other IT programs (e.g., interdisciplinary, 3-year, 2 + 2, etc.). Appendix E recognizes reviewer contributors.

Conclusion

No single procedure for success exists in producing an information technology curriculum. Although the task group believes that the recommendations and the specific strategic suggestions of the report should prove useful to a wide variety of institutions. Students of information technology should consider taking job-specific courses toward the end of their studies to arrange themselves for the skills that are current and in demand in the marketplace.

Moreover, it is important to evaluate and adjust curricular programs on a regular basis to keep up with the rapid changes in the field. Information technology curricula that already exist today are the product of several years of experimentation and refinement by information technology educators at their own institutions in collaboration with IT professionals and business and industry leaders. Future IT curricula will depend just as much on the creativity and the academia-employer partnerships that follow in the wake of this report to build even stronger information technology programs for undergraduates throughout the world.

Introduction

In this entry, how outcomes of computing education can be conceived and considered is initially

discussed. Later, returning to explore more deeply the current situation across a range of countries, identifying contemporary outcomes of computing education.

The underpinning subject area for computing education, computer science (CS), is quite a young science, which has different names worldwide. In order to demonstrate the variety of terminologies applied to this subject area, the Word Cloud of 71 (Falkner et al. 2014) shows that the words most frequently associated are computer, science, and programming. Similarly, a chart of Google Trends shows that programming and computer science terms were the most popular keywords used in the Google search engine worldwide between May 2017 and May 2018 (see Fig. 1).

In some countries, computer science is called informatics – a distinct scientific discipline, characterized by its own concepts, methods, body of knowledge, and open issues. For example, currently Korea is using the term informatics education; previously the term computer education was used until 2007, being similar to information technology (IT) education, information and communication technologies (ICT) education, and computer science education (CSE) (Choi et al. 2015). Informatics education covers the foundations of computational structures, processes, artifacts, and systems, as well as their software designs, their applications, and their impact on society (CECE 2017).

The meaning of CS has changed through the years, since it is constantly reshaped, due to new thinking approaches and emerging technologies. For example, the widely used concept of ICT has moved within ICT education from uses of ICT as a tool (with the development of digital literacy as a key requirement) toward understanding the underpinning concepts and workings of ICT (Falkner et al. 2014). So, ICT fundamentally concerns effective uses of technology.

Related to shifts in the uses and meanings of terms, it is important to focus also on the movement from using technologies as consumers to working with technologies as developers

Computing Education, Outcomes of, Fig. 1 Google Trends results

or producers (supported by digital technologies). This idea is clearly presented in the Australian Curriculum: “Digital Technologies,” which explains the differences between ICT capabilities and digital technologies (Australian Government Department of Education and Training 2018). However, having abilities in computer science is concerned not only with knowledge about computers and ICT, as computer scientists need to know much more. Thus, the focus on computing in education rather than solely on ICT is desirable (Passey 2017). In this respect, computers and the ongoing development of the internet continue to change opportunities and needs for education. Computers and networking provide opportunities for both learning and teaching enhancements, but these require users to have additional skills such as those connected with the concept of digital literacy (DL), where DL covers fluency with standard software tools and the Internet (CECE 2017). Nowadays, it is commonly agreed that such literacy is fundamental for a digitally enabled world society. The European Commission has promoted a Digital Competence Framework 2.0 as a tool to review and potentially improve citizens’ digital competence (DigComp 2016). Such competence is not only important for everyday use but also for future prospects. By 2020, for example, the ICT sector will need employees that possess and can deploy five essential skills: complex problem-solving; critical thinking; creativity; people management; and coordinating or collaborating with others. These generic skills will be essential, as technological skills for IT specialists need to collaborate with various sectors, not only within their industry

but increasingly with their users. Industry is adapting to these changing needs, so educational institutions must also adapt, as they play an important role in preparing future employees. The curricula need to be attractive (to meet the needs of digital age learners); and computing education needs to develop both technological and generic skills.

Computing education as a school subject covers all the abovementioned strands (informatics, computer science, ICT, and digital literacy). There are three main areas covered: information technology (abilities to deal with digital systems); digital literacy (abilities to use a computer confidently, effectively, and safely, with moral and ethical understanding); and computer science (developing and using algorithms, data structures, programming, systems architecture, design, and problem-solving) (The Royal Society 2017, p. 16).

In terms of outcomes (the result or effect of an action, situation, or event) of computing education, there may be impacts on learners, which might be short or long term. Educators and government are concerned with focus on the long term, as computing education needs to meet the demands of the digital age learner and to develop essential skills for life. The curriculum and global policies, in this respect, should aim to guide educators in order to develop a learner’s computing competencies for life. Such documents and policies should provide for the aims and intentions for computing education that educators translate into teaching and learning practices. However, the evaluation of such aims and intentions can be considered as a research impact assessment in itself (Esposito et al. 2018).

Curriculum and Policies

Computing education can be taught in schools in different ways. Some countries have computing-related courses as mandatory subjects, some as an elective-only subject (in Korea), but even these elective subjects can be at different educational levels (as in Lithuania, Austria, Slovakia). Some countries integrate the subject and use a multi-disciplinary approach (in Finland, France) or integrate it in all subjects and also as an optional separate subject (in Norway); others do not have such a subject or curriculum (Italy currently has no curriculum for primary education) or specific policies or guidelines (in Ireland). Thus, there are some countries where, after finishing compulsory education, learners have had no experience of any computer science-related subject.

The incorporation of CS into compulsory education has two main goals: CS helps students to acquire competencies that are necessary in current society and its strength as an element of equity to reduce inequalities of gender, race, social origin, or economic level, such as to eliminate the stereotypes that make it difficult for women to take an interest in these studies (Cabrera-Delgado 2017). The overall availability of informatics courses (elective and compulsory) in 2017 across European countries is presented in “Informatics Education in Europe” (CECE 2017, p. 14), and CS in terms of provision within the compulsory education sector in 2015 is discussed by Passey (2017).

In a number of countries, the authorities responsible for curriculum development are government ministries (in Austria, Norway, Lithuania). In Austria, the federal authorities (i.e., the Ministry of Education) have an exclusive responsibility over legislation and implementation in the entire field of education. Similarly, MEXT (the Ministry of Education, Culture, Sports, Science and Technology) publishes the government curriculum guidelines which every teacher in Japan should follow. The Lithuanian Ministry of Education and Science (MoE) is responsible for preparing the main policy documents (such as strategies and implementing

planned programs), establishes the qualification requirements for teachers working in educational institutions, and operates the procedure for attestation of principals and teachers. But in the latter case, there are additional institutions that support policy document implementation (such as the Education Development Center (EDC) and National Examination Center (NEC)). Furthermore, the MoE ensures and accounts for the quality, accessibility, and evaluation process of the system. However, ministries are less involved in some other countries. The ICT programs at national level in Spain are coordinated by the Instituto Nacional de Tecnologías Educativas y de Formación del Profesorado (INTEF), which is the ICT for education unit of the Spanish Ministry of Education (MoE). The Spanish MoE establishes a minimum curriculum for compulsory school levels which is shared by all autonomous communities, but the rest of the curriculum is developed by the regional educational authorities based on their preferences and local characteristics (Fernández 2015). In Finland, the Finnish National Agency for Education (EDUFI) operates under the Ministry of Education and Culture, responsible for developing education and training. A few years ago, both the Finnish government and local administration units (municipalities) supported the use of ICT in education, but now the Finnish education system is completely decentralized. Local municipalities are now fully responsible for ICT in schools (Kimmo 2017). Similarly, the Spanish administration is a highly decentralized system, where autonomous communities are fully responsible for the schools in their territory, which includes the promotion of ICT in schools, and they legislate under the general umbrella of national law (Fernández 2015).

By contrast, the key responsibility for the “National Informatics Curriculum” development in Slovakia is mostly assigned to Comenius University. The authors of the national curriculum include the topics of core informatics along with learning of basic ICT skills. Informatics includes computing, ICT (a set of user-oriented skills), and digital literacy (a set of basic skills to use digital

technology effectively, safely, and meaningfully to solve everyday problems and tasks) (Kabátová et al. 2016).

In other countries, state ministries are involved. Australia has eight states and territories, where each is responsible for education and has its own curriculum, although policy comes from both state and federal governments. CS, informatics, or ICT is mandated through the “Digital Technologies Curriculum” (Australian Curriculum 2017), which was mandatory in the Western Australia (DT 2017 Australian Curriculum), Victoria (Victorian Curriculum 2017), and South Australia (Curriculum in South Australian schools 2017) states in 2017 and is now implemented in other states. Similarly, Germany is a federal republic with 16 States, each responsible for their own curriculum. However, while there is no unique German CS curriculum, the German Federal Parliament (Bundestag) passed a law with regard to “Digital Education” on Digital Media Education/Informatics, Internet Policy.

In other countries, responsibilities are shared. The Directorate of Digital Technologies for Education in France is responsible for matters related to ICT, such as teacher training, preparing, giving a framework, and implementing the guidelines for the development of ICT for educational purposes in schools. The “academies,” regional structures of the French Ministry of Education, are in charge of implementing national directives and policies, which also give impetus to the development of ICT (Terrades and Chibani 2018, p. 5).

Curriculum and Primary Education

However, while national ministries and agencies play their part in what should be learned in schools and the aims of that learning (which clearly affect the outcomes of that computing education), schools also play critically important roles. Typically, schools decide which elective courses to offer, and students can choose which subjects to take. But there are some exceptions. For example, in the Korean educational system, a school chooses a few subjects that are taken by all the same grade pupils (Choi et al. 2015).

Nowadays, the trend to incorporate CS into schools from an early age is increasingly seen. Computing education can involve learning in early elementary education, which is intended to increase pupils’ exposure, attitude, and self-efficacy toward computing. Additionally, it is reported that implementing computing in early education makes pupils “happy, engaged and excited to learn” (Kind 2015). Of course, some authors argue that it is important to incorporate this subject based on pupils’ age, related to complexity of skills. It is argued that it is necessary for a child to have reached a sufficient capacity for abstraction (Cabrera-Delgado 2017), particularly at grades 9–12, or algorithmic thinking that is appropriate at grades 3–5 (Shailaja and Sridaran 2015). In this respect, informatics content and form are developed based on age, gender, or future career of pupils in Slovakia (Kabátová et al. 2016).

In primary education, computing-related subjects are mandatory in England (from 5 to 11 years of age), in Poland (1st–6th grades based on a new curriculum initiative), and in Slovakia (3rd–8th grade and optional in grades 1, 2, and 9). Computing is not taught as a separate subject in France and Finland; it is embedded in all subjects, at both primary and secondary levels. In primary schools in Germany, there is no subject for informatics, but there are ongoing initiatives and experimental projects initiated by state governments and by federal foundations, such as the GI-Working Group for CSE standards in primary education for “Competences for Informatics Education in Primary Education” which offers recommendations for development (Competences for Informatics Education in Primary Education 2018) and the GI-Working Group for CSE standards in primary education development. Similarly, in Japan, the existing curriculum does not include informatics education; furthermore, the majority of teachers do not have training in teaching informatics. However, Japan will make programming education compulsory for primary and middle schools and plans to implement it beyond 2020. To this end, a new curriculum is to be fully implemented at elementary schools from 2020, at lower secondary

from 2021, and at upper secondary from 2022. This new curriculum includes problem-solving, communication approaches, programming and simulation, information systems, as well as data processing, statistical processing, and network programming, which are fundamental technologies of artificial intelligence and the “Internet of things” (Kanemune et al. 2017). Italy has no specific national curriculum for CS for primary education; however, the Italian “National Plan for Digital Education” (Piano Nazionale Scuola Digitale – *PNSD*), a policy launched by the Ministry of Education, Universities and Research, covers all school levels and comprises 35 different actions for gradual implementation that address the five key areas of intervention: tools, skills, content, staff training, and supporting measures. The policy does not change school curricula – it proposes some innovations, such as computational thinking or coding covering all school levels. This plan encompasses the most important digital age education strands: lifelong and life-wide learning, in both formal and non-formal contexts that all together form a long-term vision (Italy National Plan for Digital Education 2016, p. 1). In Korea, computing-related subjects are elective in the elementary (5th and 6th grades) school curriculum. Such content can be found in the “life and information” section of the “practical arts” – a combination of home economics and technology and computer-related contents that are included in the technology part (Choi et al. 2015). The 5th grade student can take a subject on the characteristics of digital devices, how to use them, the traits of cyberspace, and information ethics and the 6th grade student on the meaning of information and how to explore it, together with the utilization of software.

The Lithuanian MoE also agrees that CS must be incorporated into schools at an early stage. Thus, the MoE together with the Center for Development of Education initiated the project “Informatics in Primary Education.” The project was prepared by a working group of scientists, teachers, and education experts. The primary school informatics curriculum consists of six main areas: problem-solving, digital content, algorithms and programming, information and

data, virtual communication, and safety and protection (Informatics in Primary Education 2017). Additionally, a new informatics curriculum will be developed for grades 1–10 with a special focus on the most important informatics concepts and skills (Mannila et al. 2014).

Curriculum and Secondary Education

Computing and ICT secondary school curricula vary widely. While ICT and informatics as a subject are mandatory in grade 9 in Austrian secondary schools, teacher training in this field is not mandatory. An informatics curriculum is only defined for Year 9 and as an optional subject in Years 11–13 (Spieler et al. 2017). Computing is mandatory in secondary schools in England (11–14 years of age) and elective at 14–16 years of age and is also elective at colleges (14–18 years of age) (CECE 2017). Similarly, informatics is compulsory at grade 10 in Slovakian secondary schools and optional at grades 11–13 (CECE 2017). Additionally, ICT elements are integrated across subjects (Kabátová 2016), and Slovakia is also implementing a strategy of integration of digital technologies in education through to 2020, based on “Strategic guidelines for further implementation of ICT in the Slovenian education until 2020” developed by the Slovak MoE. By contrast, a digital technologies curriculum is mandated for all levels of compulsory schooling (Years 5–10) in Australia. In most states in Germany, informatics is an elective subject at higher secondary level, more so at grades 10–13. In many states (e.g., Berlin, Bremen), schools offer informatics as an elective subject and at a lower secondary level (5th–10th grades). Only a few states already implement informatics as a compulsory subject in secondary schools; it is compulsory in the States of Bavaria for grades 6–7, in Mecklenburg-Vorpommern for grades 7–10, and in Sachsen for grades 7–8 (CECE 2017). The optional CS-related subject “technology” is available from the 7th to the 10th grade in Spanish schools. In addition, ICT is offered as an optional subject in the 10th grade. In this subject, students’ ICT competence is directly assessed, and also it is

integrated in all subjects in a transversal way (Fernández 2015). Informatics and programming as a part of a compulsory subject “Technology and Home Economics” which includes topics on computer sensing and control (with programming) are taught in Japan at lower secondary level (grades 7–9). Additionally, the compulsory subject “Information” has two elective subcategories at upper secondary grades (10–12), named “Information Study for Participating Community (Society and Information)” and “Information Study by Scientific Approach (Information Science)” (Kanemune et al. 2017). The first is about model attitudes of participation in information society and the second about scientific understanding of information (CS and its surroundings) including basics of programming and elementary algorithms (Kuno et al. 2015; Guerra et al. 2012). Additionally, MEXT promotes ICT in education under the plan to accelerate ICT (developed July 29, 2016) with a focus on utilizing ICT in the curriculum and special needs education, also improving teachers’ ability to use ICT for instructional purposes, developing children’s information literacy, promoting utilization of ICT for school administrative works, and enhancing information ethics education (Overview of MEXT 2016). As a stand-alone course, informatics is taught as an elective subject in lower and upper secondary schools (grades 8–13) in Norway (CECE 2017).

The subject informatics is compulsory in Lithuanian secondary education (grades 5–10). It is taught as a separate subject and also integrated into other subjects. The content focus is on information and technological competences development. In upper secondary schools (grades 11–12), students can select advanced optional modules.

Informatics as an elective subject is taught in Korean middle schools (grades 7–9) that covers the basic concepts and principles of CS and aims to nurture the students’ ability to observe and resolve diverse practical problems using computational thinking and the ethical attainment of information. In the high school curriculum (grades 10–12), additionally to the informatics subject (with more in-depth content), there is the

possibility to select an information science subject that focuses on connectivity with other subjects, problem-solving abilities, and programming (Choi et al. 2015).

An informatics-related subject—programming—has been piloted since 2016 as an elective subject in Norway in lower secondary schools (grades 8–10) and from 2019 as a permanent elective subject. Trials of programming and modelling in upper secondary schools (grades 11–13) have been started as well (Søby 2018). Additionally, more options on specializations in computing and programming, depending on the specific program that students choose to take, are available in upper secondary schools (Mavroudi and Divitini 2017).

Influences on Policy and Planning

Although Ireland has no national computing curriculum, policies, or guidelines, and no new educational reform was introduced in the last years, the government has launched an “Action Plan for Education 2016–2019” that states an objective to realize the potential of digital technologies to enhance teaching, learning, and assessment so that Ireland’s young people become engaged thinkers, active learners, knowledge constructors, and global citizens, to participate fully in society and the economy. Additionally, according to the “Ireland Digital Strategy for School 2015–2020,” the Department of Education and Skills will provide more appropriate support materials and services to principals and teachers on embedding ICT into their practice, as well as examples of good practice on the effective, critical, and ethical use of ICT for teaching, learning, and assessment based on a localized UNESCO ICT Competency Framework for Teachers (Connolly 2017).

While computing-related curriculum development is generally the responsibility of government (ministries of education particularly), some countries are collaborating with global companies and agencies, such as Spain with Google (Computer Science Education in Spain 2016). Google, in collaboration with the Spanish Foundation for

Science and Technology (FECYT) and Everis, have developed a report on CSE (primary and secondary schools) in Spain with the aim of introduction, extension, and improvement of the CS subject in Spanish schools (Computer Science Education in Spain 2016). In a related way, Italy has collaborated with European Schoolnet and the European Commission (Bocconi et al. 2016).

Education policies have been adopted around the world due to international dissemination of values of Western modernity and the legitimization pressures that governments receive as well as concerns for their comparative education (Verger 2014) or even competitive reasons. However, reasons for such reflections differ. In this respect, the central vision of the “Ireland Statement of Strategy” and “Action Plan for Education” is that the Irish education and training system should become the best in Europe over the next decade (Ireland Action Plan for Education 2018). Likewise, Japan MEXT comprehensively promotes science and technology (based on the “Fifth Science and Technology Basic Plan” FY2016-FY2020) with an aim to becoming the world’s most innovative country. Additionally, Spain has adopted the DigComp model proposed by the Institute for Prospective Technological Studies (IPTS) (European Commission) for any European citizen in connection with the Digital Agenda 2020 and has developed the “Common Framework for Teaching Digital Competence” – a standardized proposal which specifies a teacher’s digital competence through descriptors of 21 sub-competencies organized in 3 levels and 5 competency areas (information, communication, content creation, security, and troubleshooting) (Fernández 2015).

In England, there are three strands in the computing curriculum, which were reported on with recommendations in a Royal Society report: computer science (informatics), information technology, and digital literacy (CECE 2017). The national curriculum was developed by the government Department for Education in England, while CAS (Computing at School) prepared guidance for teachers on how computing could be implemented in schools (Kemp

2014; Berry 2013). These organizations form major parts of a national system for curriculum development, implementation, and assessment.

Curriculum Relationship to Longer-Term Outcomes

Recently, a number of initiatives, action plans, and policy drafts have appeared as a consequence of the call for a long-term vision for education in the digital age. The new “eEducation Austria” initiative of the Federal Ministry of Education (BMB) has focused on digital and CS skills, to increase the ICT competencies of all participants in Austrian schools. Additionally, the digital education strategy “School 4.0. – it’s getting digital” of the Austrian Federal Ministry of Education has been announced, with the view to making ICT and informatics mandatory in primary education (3rd and 4th grades), as well as in lower secondary (5th–8th grades) (Lehner 2017).

Similarly, the Ministry of Education of Portugal prepared the “The Student’s Profile for the 21st Century” document (approved in 2017) as a guide for strategies, methodologies, and pedagogical-didactic procedures to be used in teaching practices with the aim to clarify what is intended for young people as citizens when leaving compulsory schooling (Martins de Sousa 2017, p. 4).

Likewise, the Lithuanian MoE approved the “Students’ Computer Literacy Standard” that includes the ability to work with computers and the skills to apply IT in learning and obtaining general digital skills. Additionally, the Ministry approved “The requirements for the Pedagogues’ Computer Literacy Programme” that are compulsory for all teacher professional development programs to obtain both technological and educational ICT application competences (Brazdeikis 2017).

At a wider level, Japan MEXT works to gain public understanding of the effects and necessity of educational investment, as an investment for the future, in order to create a rich and fulfilling life for everyone and a secure society with

continuous growth especially focusing on **social competencies** for survival based on three principles of “independence,” “collaboration,” and “creativity.” Thus MEXT has promoted various plans for collaboration and cooperation between communities and schools, also enhancing lifelong learning opportunities (MEXT 2016).

Lithuanian policy focuses also on national welfare and aims to raise a young independent and innovative generation that will lead the country. To this end, goals (such as establishing an educational teachers’ community, effective interaction among stakeholders in education, accessibility and a long duration of education, and equal possibilities to all learners ensuring the system of incentives and equal conditions of lifelong learning opportunities establishment) for the national education system were set out in the key national strategic documents: “Lithuania’s Progress Strategy ‘Lithuania 2030,’” “National Progress Programme 2014–2020,” and “State Education Strategy 2013–2022” (Brazdeikis 2017).

In order to meet the challenges that are posed by wide-ranging and rapid changes in society, a revision of the national curriculum in Norway was initiated. It focuses on in-depth learning, new knowledge, and continuous skills acquisition. While the core curriculum consisted of reading, writing, oral, numeracy, and digital skills, it will be extended by three cross-curricular topics, sustainable development, democracy and citizenship, and health and life skills (Søby 2018). Moreover, digital skills (digital tools usage, critical thinking, technological understanding, basic skills, and social skills) are defined in the “Framework for Basic Skills” and in the curriculum for each separate subject, also within the digitalization strategy “Digitaliseringsstrategi for grunnsopplæringen 2017–2021” for primary and secondary education for 2017–2021, published by the Norwegian Ministry of Education.

Similarly, the Council for Informatization of Education in the Polish Ministry of National Education initiated a curriculum revision for computer science education to cover all school levels across grades K to 12. The curriculum has

three parts: unified aims (understanding and analysis of problems; programming and problem-solving; using computers, digital devices, and computer networks; developing social competences; observing law and security principles and regulations), purpose of study, and attainment targets. In order to encourage and motivate students to make personal choices, some optional attainment targets (freely added to a subject syllabus or assigned only to a group of students) are involved in the curriculum. Based on this new curriculum, informatics is a compulsory subject in primary schools (grades 1–6), middle schools (grades 7–9), and high schools (grade 10) and is an elective subject in high schools (grades 11–12); students may graduate in informatics when taking the final examination (Syslo and Kwiatkowska 2015).

In such policies and guidelines, computational thinking is a concept that plays an important role in future curriculum adoption. The vision for the development of capacities associated with computational thinking and digital literacy to foster cross-curricular competencies was presented in Portugal project - “1st cycle Primary School Programming Initiative” (Martins de Sousa 2017, p.12). Additionally, Portugal has started an initiative to create ICT as a subject from the 5th to the 9th grade; currently it is available in grades 7 to 8. ICT is defined as a subject with the aim to foster a learner’s critical analysis of information and to develop the ability to research, process, produce, communicate, and collaborate through technologies (Martins de Sousa 2017, p. 22).

A focus on digital competence assessment is planned in France from September 2018 across primary schools to universities. “The Common Framework of Digital Skills” modelled on the DigComp (“The Framework for Developing and Understanding Digital Competence in Europe”) will replace the “B2I” (The Internet and Information Technology Proficiency Certificate) created in 2001 (Terrades and Chibani 2018, p. 13). Since it includes notions of basic/independent/proficient users in different domains, it is intended to enhance the future employability and mobility of today’s students. Similarly, the Lithuanian MoE developed a law on digital literacy for primary and

secondary education based on “DigComp 2.1: The Digital Competence Framework for Citizens with eight proficiency levels and examples of use” and for teachers’ education based on the “DigCompEdu: European Framework for the Digital Competence of Educators” (Order No. V-598 2018).

Curricula Content

The content of the various computing-related curricula is quite different across countries. However, there are details in common. The majority include digital competence or digital literacy frameworks. For example, digital competence plays a fundamental role in Portugal where ICT is taught as a subject in grades 7–9 (Martins de Sousa 2017, p. 22). Some countries have a clear emphasis on the information processing area or a focus on programming (France, South Africa). By contrast, the CS curriculum in Austria covers basic competencies in dealing with technologies such as Microsoft Office products or descriptions of learning about basic principles of automata, algorithms, and programs (Spieler et al. 2017).

In Australia, digital technologies comprise three related strands:

- Digital systems (identify and explore digital systems (hardware and software components) for a purpose)
- Data and information (recognize and explore patterns in data and represent data as pictures, symbols, and diagrams; collect, explore, and sort data, and use digital systems to present the data creatively; independently and with others create and organize ideas and information using information systems, and share these with known people in safe online environments)
- Creating digital solutions (follow, describe, and represent a sequence of steps and decisions (algorithms) needed to solve simple problems, explore how people safely use common information systems to meet information, communication, and recreation needs) (AC DT Structure 2018a)

Additionally, the key concepts of abstraction, data collection, representation and interpretation, specification, algorithms, and development correspond to the key elements of computational thinking (AC DT Learning in Digital Technologies 2018b).

Finland’s new national curriculum has a clear emphasis on computational thinking. The central aims of the new curriculum are to develop the school culture and to promote instruction with an integrative approach. Thus pupils will be able to understand and combine knowledge and skills from different subjects and collaborate (Finnish National Board of Education 2016). ICT competences will be assessed as a part of subject-based assessment; no separate grades or certificates will be given (Kimmo 2017).

In France, computer science covers algorithms, machine, language, and information concepts that were used as a framework for the ISN (Informatique et Sciences du Numérique/IT and Digital Sciences) syllabus, which is accordingly structured into four themes: data representation, algorithmic, languages and programming, and computer architecture (Baron et al. 2014). These themes characterize computational thinking. There is no separate ICT subject in France; however, it is included in EMI (Education aux Médias et à l’Information – Education for Media and Information Literacy which integrates the notion of critical thinking) and an optional subject called ISN that includes computer programming, e-safety, accessibility, and algorithms. Additionally, education for media and information literacy is part of the curricula in lower secondary schools that enable learners to understand and use media, tools, and digital resources independently and in compliance with the law, such as protection and respect for privacy, intellectual property – controlling one’s image – and responsible behavior (Terrades and Chibani 2018).

Although Finland does not have an autonomous CS curriculum, the core curriculum describes seven transversal competences (construction of knowledge, skills, values, and will) that include ICT competence and multi-literacy. It also provides for teachers the criteria

for assessment at the end of grade 6 and the final assessment in grade 9. It is believed that this assessment supports pupils as lifelong learners (Finnish National Board of Education 2016). The necessity to adopt to the digital world can be seen in current Spanish educational law. According to this, ICT competence involves generic skills: creative, critical, and secure use of information and communication technologies to achieve objectives related to work, employability, learning, use of free time, inclusion, and participation in the society. Of course, it requires subject-related skills: textual, numerical, iconic, visual, graphic, and sound as well as their patterns of decoding and transfer. This involves knowledge of the main tools and also access to sources and information processing, as well as knowledge of the rights and freedoms of people in the digital world. The Spanish curriculum is arranged in subjects, and its main elements are the objectives, competences, contents, methodological approach, learning standards, and evaluation criteria, with reference to the “European Key Competences Framework” (Fernández 2015).

Similar topics in the English and Slovakian primary education informatics subject include information around us; communication via ICT; methods, problem-solving, and algorithmic thinking; principles of ICT; and the information society (Kabátová et al. 2016). Primary education informatics is identical to basic schools’ informatics. Furthermore, it contains the list of requirements for learners, such as the need to understand the concepts of CS; developing the skills to algorithmize an assigned task, collaboration, and programming skills; learning to comply with regulations on intellectual property; and developing their personality, creativity, and logical thinking (Bučková and Dostál 2017).

The documents discussed above clearly show that countries focus on digital age requirements, and to this end various strategies are applied in the education sector for its improvement. Some countries are following others’ examples, while some rely on international and/or local experts’ opinions. However, there are many issues to overcome in order to effectively and successfully implement all strategies. All responsible

authorities of education (at least in a country) must form one well-interconnected system with each owning their responsibilities and duties, such as curriculum and strategy developers, teacher trainers, and evaluators. Additionally, instruments and responsible authorities for measuring outcomes of computing education play an important role for education sector improvement: either by evaluating the outcomes for new strategy development or by providing good examples and tips.

Furthermore, despite England being one of the leaders in computing education, it still faces challenges, such as teachers’ lack of confidence in computing and CS as an overwhelmingly male-dominated subject and workforce; making computing education compulsory will not automatically lead to a higher proportion of young women choosing it (The Royal Society 2017).

Countries are redeveloping their curricula and guidelines in order to meet the demands of the digital age learner. However, to successfully implement all these policies, there are many factors to consider. For example, Korean education prepared a new computing curriculum, moving from computer education to informatics: “the focus on mere functional education on application software was reduced and contents on problem-solving methods and procedures, algorithms, and programming was strengthened with a view toward enhancing the understanding of computer science.” The adverse capabilities of computers spread, and content related to information ethics was reinforced (Choi et al. 2015). However, after ICT education guidelines were abolished, the selection rate of computer-related subjects dramatically decreased: less than 10% of middle and high schools offer informatics classes, and less than 5% of students have the opportunity to take an informatics class at school (Choi et al. 2015). Additionally, decreased time for elective subjects and absence of CSE evaluation are also reasons for the lower priority among elective subjects.

Korea evaluates students’ knowledge and competencies (listed in the curriculum) through written tests and their performance, respectively. The performance evaluation is usually weighted higher than the written test. They are also

planning to benefit from existing CSE evaluation studies, such as ICILS (International Computer and Information Literacy Study) that examines the outcomes of student computer and information literacy (CIL) across countries or TOPCIT (Test of Practical Competency on IT) that assesses the competency of IT human resources (Choi et al. 2015).

In Lithuania, the National Examination Center (NEC) is working in the area of computing education-based assessment. The maturity examination assesses students' skills grouped as follows: knowledge and understanding (lower-level skills); knowledge, technologies, and techniques application; problem-solving; and communication. Abilities to apply are weighted higher than other skill groups (it is 60% of the final evaluation). The content is based on the IT curriculum and involves four main activities: safe and lawful use of information and the Internet, working with text documents, processing of numeric information in a spreadsheet, and programming. Thus, students take written tests and performance tests (programming, documents management) (Order no.V-9 2018).

ICT and digital competence are integrated in all subjects in Norway. ICT-based assessment is offered in both lower secondary and upper secondary schools in Norwegian education (primary education has no centralized assessment). Some subjects offer a two-part examination in which the first part has no access to tools and the second part includes the use of ICT/internet (Søby 2018).

Curriculum and Country Features Summary

A summary of the country features of curricula discussed above concerned with computing education initiatives is presented in Table 1.

Computing Education and Teacher Training

Teacher training plays an important role in successful curriculum implementation. It is one of

three determinant factors in order for CS to meet the current needs of a digital society, along with curriculum adoption at different ages and the provision of sufficient technical and curricular resources for teaching staff (Cabrera-Delgado 2017). Teachers are the key people who implement and deliver curriculum to classrooms. Thus, Poland has developed CSE standards for teacher preparation, focusing on teachers' engagement in professional development and certification procedures for a teacher's work evaluation in order to support the teacher in better preparing for teaching CS (Syslo and Kwiatkowska 2015). Moreover, the experience in France shows that the administrative demands on teachers was one of the factors that led to a new discipline, i.e., informatics, to decline (Baron et al. 2014). Additionally, there was a lack of necessary knowledge for assessing students' competences, so teachers failed to successfully implement schemes for ICT skill certification proposed by the Ministry of Education of France in 2001. Nowadays, it is reported that there are many opportunities for French teachers to get support and certification in digital competencies development, provided by different authorities, such as the Higher Schools for Teachers, Ecole Supérieure du Professorat, and Regional Education Authority of Créteil, Académie de Créteil. Moreover, ICT in initial teacher education is compulsory (Terrades and Chibani 2018).

Many countries agree that teacher training is fundamental. Some have already implemented training courses; others are implementing new strategies such as "School 4.0. – Now it's digital": Austria's teachers are now offered an opportunity to attend qualification seminars for Microsoft Office Specialist and to obtain certificates for digital competencies and media competency in order to be able to pass them on to pupils (Lehner 2017). Previously, teachers were insufficiently trained for applied CS education because of the lack of programs for CS education in universities and the lack of the literature on practical, state-of-the-art examples for implementing CS education (Spieler et al. 2017). Similarly, in Ethiopia, the main challenge to deploy ICT in schools is to train teachers adequately and thus to ensure the quality of ICT education to make it accessible (Ethiopia (ICT)

Computing Education, Outcomes of, Table 1 Summary of intentions of computing-related courses

Country	Grade													Comments
	1	2	3	4	5	6	7	8	9	10	11	12	13

Policy and Strategy 2016, p. 17). Consequently, students will develop ICT and higher level skills necessary for future employment in computer-related occupations in Ethiopia. Thus, Ethiopian government strategy is to update school curricula by including ICT courses, moreover to ensure ICT availability across all levels of the school system.

Teacher training and educational policy objectives can have direct interconnection. This is clearly indicated in Norway, where the government focuses on increasing teacher competence and improving the status and attractiveness of the teaching profession. To this end, the strategy “Promotion of the Status and Quality of Teachers– a joint effort for a modern school of knowledge” was developed with an idea to provide all students with the skills, attitudes, and values for life management, successful

participation in society, workplace, and community (Søby 2018). Additionally, pupils and teachers are required to use ICT across all school subjects at all levels of school (Røkenes Krumsvik 2016).

Conclusion

In order to successfully implement computing education, it is necessary to develop an appropriate system of policies, guidelines, teacher training, and evaluation with clearly defined responsibilities. Relevant support for teachers – training, infrastructure, and teaching content – is necessary. Additionally, understanding the pedagogies and assessment methodologies that underpin computing education will help teachers

improve pupil outcomes, and an adequate infrastructure for schools is crucial.

While policies mostly suggest the need to assess the skills or competencies of learners, there is a lack of models or clear assessment criteria and guidance for teachers showing them how to implement curriculum and how to assess students.

Introduction

Writing a contribution about practices of computing education is an intriguing but inherently challenging task, and an entire encyclopedia for itself could be elaborated on this subject.

One aspect of this endeavor is the abundance of teaching methods and approaches in classroom settings, and the other is, generally seen, the phenomenon of learning itself and in special teaching and learning in the field of computing. This is still far from being as settled and resting in itself as other traditional disciplines (e.g., languages, mathematics, science subjects, the humanities, arts, and music). As a consequence the following comprehensive summary cannot go into the detail of singular practices in classroom teaching but puts emphasis on an attempt to structure a very wide field without omitting its theoretical foundations.

In contrast to theoretical and prescriptive issues of computing education, including the wide field of teaching methods, rather little is known about what is really going on in classrooms during computing lessons.

The young school subject computing is still occupied with itself and the consolidation of its contents. With the still rapid changes, computer science teaching runs the permanent risk of dealing more with technologies and products than with the underlying educational content (Hartmann 2010). The role of the computer as a didactic medium on the one hand and computing

as a subject of instruction on the other is hardly kept apart, which makes it difficult to reach a common understanding on the subject and its differentiation from other subjects.

However, the computing curricula, educational standards, and reference frameworks currently being developed in many countries signal an increasing stabilization and clarity of content. Should these curricular efforts lead to a situation in which the school subject of computing can rest in itself without following every fad, this will not, however, mean the end of didactic approaches. The challenge for providing good practices in computing education and to convey a distortion-free and complete picture of the discipline will remain, and the focus will shift from “What and when to teach computing?” to “Teach how?”

What Is Computing Education?

Computing is the overall broad subject (area) and encompasses three related areas (Furber 2012):

- Computer science (CS) consists of theoretical concepts and practical skills, including the study of algorithms, coding, data structures, system architecture, and problem-solving, nowadays also embracing computational thinking.
- Information technology (IT) is industry related and deals with preexisting informatics systems (hardware, software, networks). IT helps us to solve a problem through appropriate choice, (re)use, and configuration of digital artifacts. It includes the use of technology in many fields as science, business, health care, and creative arts and requires good knowledge about IT systems, human factors, design issues, project management, and so on.
- Digital literacy (DL) can be defined as the skill which we might expect any school leaver to have just as reading, writing, and calculating. Covering competences (skills and knowledge) to use computers safely and effectively, DL can be seen as a required cultural technique to extend natural human abilities. It does not replace traditional reading and writing skills,

but it does build upon them. DL is the ability to understand, assess, evaluate, transform, and create information using digital media.

In order to illustrate these areas, the following questions may be asked when considering the task “creating and publishing a web page” (Simmons and Hawkins 2015):

CS: What is HTML? How is HTML rendered as a web page? How does a web page find its way from the client to the server? What is the essence of Cascading Style Sheets, and where can you find this concept in other application software?

IT: How do you host web pages; what hardware and software are needed? How do I choose the best software to make web pages? How do I choose and optimize graphics for quality and fast download?

DL: What are the steps to create a web page using a software package? How do I edit text and graphics? How do I include a video?

Theses on Contemporary Practical Computing Education

Modern information and communication technologies have a lasting impact on the lives of young people and demand new, far-reaching skills in dealing with digital media and information processing technology. They are of central importance both for the individual to cope with life and social participation and for the future viability of every country. But what is modern computing teaching and learning about (Breier and Alisch 2014)?

Computing Education is:

1. General Education

Aims and contents are always a reflection of political and economic conditions. Nature sciences have developed their full recognition comparatively late in the end of the nineteenth century. Laws of nature were discovered over material and energy. Today computer science forms the core of the next digital revolutions and is the basis of contemporary and future technologies, impacting our society. Computer science as a science and the subject computing as its educational mirror play a key role in automatic and

increasingly autonomous information processing and knowledge representation (GI 2000).

2. Information-Oriented

In modern computing lessons, information is at the center as the third basic quantity of nature; it can probably be distinguished from the other two quantities, matter and energy (Aßmann and Ungerer 2011). From the point of view of general education, the information-oriented pedagogy approach puts teaching computing close to the classical natural science subjects and justifies its implementation to the mathematical-scientific-technical area. Computing education is not primarily limited to the operation of devices and software in selected applications, but students acquire background knowledge about the basics, methods, applications, working methods, and the social significance of computer science systems. In addition to information, communication, cooperation, model, algorithm, computer science system, language, and automaton are further guiding concepts of information-oriented teaching. In this understanding, computing builds bridges to the social and societal sciences and at the same time opens up to media education. Digital media themselves become the subject of teaching.

3. Competence-Oriented

Competence orientation puts the outcomes and results of learning into the foreground action, practically applicable and of personal and social significance. In the educational plans on which modern computing education is based, the competences to be acquired by the pupils can be aligned to educational standards. The principles and standards for computer science in schools recommended by the GI in 2008 (GI 2008) provide a suitable basis for this.

4. Context-Oriented

Contemporary computing teaching uses innovative teaching concepts such as IniK (Informatik im Kontext) (Computing in Context, Diethelm et al. 2011). IniK is based on the assumption that solely technical computing competences do not suffice to understand

the digital world of IT systems and digital media and to be able to use them in a self-determined way. To this end, questions are placed at the center of computing that go beyond technical issues and include the social context, aspects of economics, culture, politics, or law (Coy 2005). Answering these questions makes it possible to develop IT content in a cross-disciplinary way and can lead to sustainable computing competences.

5. Media-Related

Contemporary computing teaching takes into account that computer science education and media education are two complementary, mutually dependent tasks of every school education. The fact that their fields of activity do not overlap is due to the nature of new digital media. From a technical point of view, they are IT systems that consist of hardware and software and are linked to the Internet as the leading medium.

Today, the contribution of computing and media education no longer lies solely in the provision of basic computer methods but also in the fact that digital media themselves become the subject of computing teaching and that pupils acquire simultaneously media competence. This is possible through an appropriate selection of contexts (cf. thesis 4). Typical comprehensive topics could be:

- E-Mail (only?) for you.
- My computer is talking to me!
- Smart and rich through apps.
- Cyberbullying.
- Social networks.
- Don't trust a picture!
- Mobile Internet – always and everywhere reachable?
- Computer games – between fun and addiction among other things.

Some of these have already proven their value in class and have shown that they are particularly appealing to schoolgirls.

6. Gender-Sensitive

Gender-sensitive teaching computing is characterized by a learning environment which is equally suitable for pupils and encourages them to discover their own talents

and strengthen their self-confidence. Computing lessons take into account the fact that female pupils have on average less experience in using (desktop/laptop) computers (but not smartphones) than male pupils and ensure that these differences are not intensified but reduced. Contexts are helpful (see thesis 5) that especially appeal to girls. "One key, in our opinion, lies in the focus with which the study of the contents of computer science is taught. Experience shows that the majority of female pupils and students are not interested in technology 'in itself,' but in technology 'for what.' The application contexts and the design of technology in response to these motivate them to deal equally with technology and the contexts" (Schirmer 2013). It is precisely the design of technology and the creativity associated with it that take on special significance in gender-sensitive computer science teaching, as various studies indicate that women and girls can gain an interest in computer science with the help of creativity (Romeike 2008).

Furthermore, gender-sensitive computing teaching focuses on gender equality. For computer science lessons, gender equality means always tracking and breaking down the effects on pupils with regard to their outdated and "traditional" role attribution. To this end, teachers have to analyze tasks or IT projects from both gender perspectives. The projects should always contain attractive and creative elements for both sexes in equal proportions, so that both sexes can learn the necessary computing competences (modelling, implementing, etc.) within the respective subtasks.

7. Language Teaching

Languages play a very important role in computing teaching. Their conscious use offers many opportunities to build up sustainable linguistic competences, thereby different language levels (everyday, educational, technical). Language skills are systematically built up in computing lessons by giving pupils the opportunity to present complex interrelationships orally and in writing in a variety of ways.

Computing teaching supports the development of general language competence among pupils. Volker Claus recognized this as early as 1995. He postulated computer science teaching as language teaching and suggested that “the analysis and use of languages of all kinds, starting from computer science languages, should form the general core for the newly (1995) oriented school subject of computer science.” Computer science does not prefer any special language: norms, program sequences, drafts, specifications, etc. are presented in natural languages; algorithms, data structures, or objects are usually described in semiformal languages, mathematical calculations are used for theoretical questions and modelling, and programs must ultimately be formulated in an artificial language (Claus 1995).

8. Interdisciplinary

Lessons according to “Computing in Context” are per se interdisciplinary, subject-linking lessons. Assuming a real-life context, there are manifold references to different subjects. Probably only a few teachers are able to deal with multidisciplinary challenges with professional competence. Appropriate interdisciplinary teacher training in which colleagues from the relevant subjects join together to form a team may be the key. In interdisciplinary teaching, which must be mastered by a single teacher, the “courage to fill a gap” is recommended (Diethelm et al. 2011).

9. Project-Oriented

A pedagogical project “represents the joint attempt by teachers, pupils, parents, experts, etc., to connect life, learning and work in such a way that a socially relevant topic or problem can be dealt with within and outside the classroom, which at the same time corresponds to the individual needs and interests of teachers and pupils. The work and learning process triggered and organised by the project idea is as important as the outcome or product to be achieved at the end of the project. Projects open up the opportunity to remove the

socially prescribed separation of headwork and manual work to a certain extent” (Meyer 1987).

At the center of each learning project is an exemplary context, with which the pupils deal in a creative way and develop theoretical concepts and contents within these projects. The context is chosen in such a way that the pupils need to acquire competences from as many areas of competence as possible. When selecting the contexts, the students’ interests and performance as well as the perspectives already postulated in theses 4, 5, and 6 are taken into account. Teachers ensure that different learning interests are not ignored. If possible, the pupils will be involved in the selection process.

10. Binding for All Pupils

In the twenty-first century, digital competences have at least the same significance as competences in the classical natural sciences of biology, chemistry, and physics (cf. thesis 1). For a reliable implementation, computing teaching needs political commitments. The short history of schools gives evidence that without a subject computing in its own right, the systematic promotion of corresponding competences cannot be guaranteed.

Future generations will move in an environment that is largely shaped by information technology. By then at the latest, mastery of computer science methods and tools will be the fourth cultural technique alongside writing, reading and arithmetic. But this also results in a central, not only technical, but above all social task: namely to enable all people to handle their data in a self-determined way and to guarantee this. (GI 2006)

The future of computing lessons characterized in these theses requires a rethinking of politicians and teachers. Many countries are making already good progress in devising corresponding computing curricula and implementing the subject computing in schools. But there is still a long way to go in order to transform the theory of (necessary) computing education into good practices at classroom level.

From Curricula to Delivering Lessons

A curriculum can be seen as a contract between society, politics, and schools/teachers about the way of organizing and providing sequences of learning experiences aimed at producing desired learning outcomes. The curriculum reflects the kind of society to which we aspire. In the simplest terms, “curriculum” is a description of what, why, how, and how well students should learn in a systematic and intentional way. The curriculum is not an end in itself but rather a means to fostering quality learning (UNESCO 2013). Another definition describes the curriculum as all planned learnings for which the school is responsible and all the experiences learners have under the guidance of the school. Curriculum is the totality of learning experiences provided to students so that they can attain general skills and knowledge at a variety of learning sites (Marsh and Willis 2003). Put in the simplest way, a curriculum is a course or plan for learning (Taba 1962).

An ambitious attempt to put curriculum issues in a broader context, the “Darmstadt Model” has been developed for comparing computing education in different countries. Within these comprehensive model terminologies, goals and competencies, content issues, programming languages, assessment, and teacher education and trainings, also teaching conditions and practices are included.

This model shows impressively the complexity of implementation issues and the practices of computing education in a single country. Herein, “curriculum issues” are (only) one of 13 identified factors in the dimension “educational relevant areas.”

Inherently, every model has limitations, reduces complexity, and mirrors reality often only in narrow contexts. Curriculum issues and curriculum reforms cannot be judged without looking at the educational system, educational governance and the sociocultural background, and, as mirrored in the model, its range of influence.

Since some years, in many countries curricula are interwoven with competence models and

Computing Education, Practices in, Table 1 Typology of curriculum representations

Intended	Ideal	Vision (rationale or basic philosophy underlying a curriculum)
	Formal/written	Intentions as specified in curriculum documents/materials
Implemented	Perceived	Curriculum as interpreted by its users (especially teachers)
	Operational	Actual process of teaching and learning (curriculum-in-action)
Attained	Experiential	Learning experiences as perceived by learners
	Learned	Resulting learning outcomes of learners

educational standards. Not least due to the disappointing results of international comparative studies such as TIMMS and PISA about 20 years ago, educational experts in many countries brought up the idea and concept of outcome orientation and educational standards.

There are different views on curriculum levels. The intended curriculum is content specific by the state, district, or school to be addressed in a particular course or at a particular grade level. The implemented curriculum is content actually delivered by the teacher, and the attained curriculum is actually learned by the students (Marzano 2003).

Table 1 illustrates the long way from the intended curriculum to its way into the brains of the learners where effective curricula with the status “attained” leave something magic called “competence” (Akker 2010). In extension to the Darmstadt Model in Fig. 1 and its axis “Level of Responsibility/Range of Influence,” a differentiation between various levels of “curriculum responsibility” could be useful when discussing computing education in view of curricular activities. These stages are top-down as follows: supra (international, comparative), macro (system, society, nation, state), meso (school, institution, program), micro (classroom, group, lesson), and nano (individual, personal).

Computing Education, Practices in,

Fig. 1 Darmstadt model (Hubwieser et al. 2015)

Clear objectives and measurable learning outcomes are at the core of the idea of competence orientation. This is represented by the top dimension “consequences” of the Darmstadt Model, whereas the operational and experimental stage can be subsumed under the “decision area,” the “battle zone” in the class where the curriculum meets pupils in concrete lessons.

Teaching Models

The majority of scientific contributions to computing didactics deal with subject-specific and content-related aspects. (Empirical) studies about practices of computing teaching are the exception, and aspects of teaching organization and the conditions of computer science teaching (media use, teaching materials, and teaching methods) are still a research desideratum. Despite its special position as a young, dynamic subject, computing undoubtedly obeys the logic of subject-independent teaching models in general, in which determining parameters become transparent by reducing the reality of teaching. Every didactic activity, both traditional and reformed, takes place between teachers and pupils who pursue teaching objectives based on selected themes (what should be learnt when?).

In the often quoted didactic triangle of relationships according to Herbart’s teaching theory

Computing Education, Practices in, Fig. 2 Teacher-centered model

(nineteenth century) “pupil-subject-teacher,” the complexity of teaching is only inadequately expressed. However, even a somewhat expanded model (Fig. 2) makes visible those structures that can be used to better reflect the reality of teaching. The perception of learning processes decisively shapes the understanding of the teacher’s role and thus the positioning, networking, and perspective in the didactic triangle. It is time to focus not only on the currently dominant content dimension but also on the actors in the teaching process, i.e., learners and teachers.

The key to good teaching is finding this balance between structure and agency, which is the great challenge of education. There is a constant

tension between agency (what learners do) and structure (how the context is constrained).

A look beyond the boundaries of computing didactics to physical education (sports) as a teaching subject suggests the extended teaching model shown in Fig. 2. This puts the teacher at the center of the teaching. *Prima facie* directed against the mainstream of constructivist learning theory, this model (Scherler 2013) makes sense, especially in view of the similarities between sports and computing teaching. In both subjects, special equipment (media) and teaching conditions play an important role. Scherler stresses the coherence and fits concerning the interdependencies presentation (content), organization (conditions), and interaction (pupils). Presentation, interaction, and organization have to be coordinated as well as possible, which fall under the sole responsibility of the teacher and have an influence on the quality of the teaching. The more freedom that teachers offer learners, the more they need to think about the constraints of the established learning environment.

In order to teach better, we need to understand the students' thinking. Teachers often fall into the expert's trap to assume too much prior knowledge and to fail to make explicit the knowledge that is implicit to experienced teachers. Good teachers can predict the pupils' misconceptions. Research confirms that "students' scores showed the most improvement when teachers were able to predict their students' wrong answers" (Reuell 2013).

Rather than thinking like an expert, it is necessary for teachers at the lesson planning stage to think like a novice.

Teachers need to have an understanding of what makes the learning of specific concepts easy or difficult: the conceptions and preconceptions that students of different stages and backgrounds bring with them... if those preconceptions are misconceptions, which they so often are, teachers need knowledge of the strategies most likely to be fruitful in reorganizing the understanding of learners.

The most effective teachers have deep knowledge of the subjects they teach, and when teachers' knowledge falls below a certain level, it is a significant impediment to students' learning. As well as a strong understanding of the material

being taught, teachers must also understand the ways students think about the content, be able to evaluate the thinking behind students' own methods, and identify students' common misconceptions.

Computing does need explicit teaching and subject-specific pedagogy. Findings in cognitive psychology are the key to improved learning as a result of certain teaching practices.

Extensive research recommends that a curriculum needs to be spaced and interleaved and should include frequent practices (Lau 2018). Further a curriculum is best structured around problems to be solved, and a good way to frame lessons is through carefully designed fertile and deep questions.

Based on the comprehensive theory of instructional design, there are ten research-based instructional principles that teachers should use (Rosenshine 2012):

1. Lesson starts: Begin a lesson with a short review of previous learning (low-stake testing, questioning to address misconceptions, etc.).
2. Present new material in small steps with student practice after each step.
3. Ask a large number of questions and check the responses of all students.
4. Provide models.
5. Guide student practice.
6. Check for students' understanding.
7. Obtain a high success rate.
8. Provide scaffolds for difficult tasks.
9. Require and monitor independent practice.
10. Engage students in weekly and monthly reviews (exit tickets, low-stake quizzes, summative assessment).

The structurally identical, but with regard to the distribution of roles learners/teachers modified, model places the learner at the center of the teaching process. Here the teacher acts as a teaching companion or learning designer and catalyst, who also explicitly considers the methods, teaching materials, or media (how is learning done?) and is responsible for the learning conditions. This learning arrangement is the basis of the

Computing Education, Practices in, Fig. 3 Pupils-centered model

“new tube” of research-discovering learning in the classroom, with which “old informatic wine” comes or should come into the heads of teachers and students (Fig. 3).

Students do learn cognitive processes through experience and the failures they are making, finding and avoiding them, and trying not to repeat them. When they avoid an error that they know they have made previously, they can say that they have learned.

They learn by doing, that is, they learn from thinking about those experiences. When they have understood the experiences well enough, students can (unconsciously) index them so that they will come up again just in time when they need them again. Students do not learn from memorizing answers. They learn from developing questions for themselves that they then can begin to find answers to (Schunk 2011).

Learning Theories

Behaviorism

The principles of this theory can be found in schools with positive discipline systems that seek to modify behavior through rewards and sanctions. In computing, game-based learning can create similar results when players are rewarded for correct answers. Many quiz (responsive) systems can be assigned to this learning

theory which goes back to the famous Pavlov’s experiments involving dogs, food, and bell ringing.

Cognitivism

Piaget identified cognitive development structures whereby individuals create their own internal knowledge structure (schema) and then attempt to classify new information into the existing schema (assimilation) or develop new schema if it does not fit within the existing structures (accommodation). Cognitivism is primarily concerned with the way in which learners gain knowledge. This is usually fundamental in the computing field as the ability to create and manipulate knowledge is at the core of what the learners do. Effective tutoring systems are based on this theory.

Constructivism

Individuals construct their own knowledge. A person’s interpretation of knowledge is influenced by their experiences, environments, and beliefs.

In the classroom, the constructivist view of learning implies various teaching practices. It usually means encouraging students to use active techniques (simulations, experiments, real-world problem-solving) to create more knowledge and then to reflect on and talk about what they are doing and how their understanding is changing. The teacher makes sure he/she understands the students’ preexisting conceptions and guides the activity to address them and then build on them (Oliver 2000).

Constructionism

It builds on constructivism by suggesting that individuals construct particularly effective mental models when they make a meaningful product. Coined by Seymour Papert, the term was particularly applied and investigated through IT-mediated learning. Nowadays constructivism closely connects with the ideas of playful and problem-based learning. Block-based programming environments as Scratch, App Inventor, and the Maker Movement are based upon constructionist principles.

It is plausible that different types of learning match to different appropriate learning theory approaches.

Introductory Learning

Learners have little directly transferable prior knowledge about a skill or content area. They are at the initial stages of schema assembly and integration. At this stage classical instructional design is most suitable because it is pre-determined, constrained, sequential, and criterion-referenced. The learner can develop some anchors for further exploration.

Advanced Knowledge

Acquisition follows introductory knowledge and precedes expert knowledge. At this point constructivist approaches may be introduced.

Expertise Knowledge

Acquisition. In this stage the learner is able to make intelligent decisions within the learning environment. A constructivist approach would work well in this case.

This is a rule of thumb, and it is still important to consider the context before recommending any specific methodology.

Planning and Structuring Lessons

Lesson planning is likely to have the greatest impact on teaching and learning. The crucial point is aligning the teachers' subject knowledge with their pedagogical content knowledge. As teachers learn how to best teach their subject, they will continue to develop their pedagogical content knowledge both consciously and subconsciously. They will find out what works and what does not work. Shulman, who coined the term "pedagogical content knowledge" (PCK), refers as follows:

Within the category of pedagogical content knowledge I include, for the most regularly taught topics in one's subject area, the most useful forms of representation of those ideas, the most powerful analogies, illustrations, examples, explanations, and demonstrations – in a word, the ways of

representing and formulating the subject that make it comprehensible to others. Since there are no single most powerful forms of representation, the teacher must have at hand a veritable armamentarium of alternative forms of representation, some of which derive from research whereas others originate in the wisdom of practice. (Shulman 1986)

Instructional design is the science of creating instructional curriculum that is geared toward producing specific learning outcomes, based not only on pedagogical research but also on current instructional practices. Instructional design is useful in producing effective lesson planning and designing (computing) courses. While the implementation of certain technological resources can enhance and enrich learning outcomes, the end goal is effective instruction, not the production of technology-rich materials. In essence, then, the role of instructional design is to create instructional experiences that facilitate the acquisition of knowledge in a way that is not only efficient but effective and appealing to learners. As a framework for developing learning modules, the focus of instructional design is on enhancing the learning acquisition process with the goal of engaging, encouraging, and motivating learners to gain deeper, more significant, and more meaningful levels of understanding and knowledge. This cooperative and collaborative method makes students dependent on each other to succeed and fosters in the best case social learning.

Dimensions of (Computing) Lessons

In general, there are four major components to be considered when creating any form of course or learning activities and lessons:

Learning tasks – ensuring skills, knowledge, and attitudes are covered in sequential ways, moving from easy to difficult, using, when appropriate, so-called real-world tasks, reducing scaffolding with each subsequent task and varying form of practices
Supportive information to accompany them – bridging links between tasks, explaining how

to approach problems and questions, offering strategies to consider, and showing how the domain (the big picture) is organized

Procedural information to accompany them – what is needed before tasks can be attempted, what should be practiced, how to undertake any routines needed, and any step-by-step instructions needed

Part-task practice – providing more practice tasks so learners can gain a level of automaticity in undertaking them, offering repetition, once a real-life task has been completed (Passey 2015, cit. Van Merriënboer and Kirschner 2012)

The underlying educational questions of curricula down to concrete everyday lessons are who should learn something from whom, when, with whom, where, how, with which means, and what for. Based on these basic fundamental questions of general pedagogy, six dimensions can be distilled for every lesson planning. Between all these dimensions, there are mutual interdependencies. Results of studies show that learning goals on a theoretical level play a central role for teachers and that goals and objectives should be the starting point for all planning considerations (Fig. 4).

Content and Objectives

It is self-explanatory that “content is king” – an often cited quote in the world of online marketing – applies also to subject learning when it comes to education in formal settings.

In Fig. 5 an attempt is made to allocate content to the three strands of computing education (Lau 2018, p. 4). But education refers also to social learning which can be influenced and supported by student-centered cooperative teaching methods.

Most (old) curricula were centered around an age-appropriate structured body of subject-specific content. Nowadays, competence- and outcome-oriented curricula and syllabi define in different granularity general goals and detailed objectives as well.

In computing lessons concept and product knowledge, competences and skills are imparted. For the learners (and sometimes also for teachers), the main goals of their teaching stay often unclear. They are in danger to get lost in details.

Clearly formulated goals help them to keep an overview of the field (Hartmann 2006).

One seminal work about the classification of objectives is the Taxonomy of Educational Objectives (Fig. 6. Anderson and Krathwohl 2001).

educational objectives

(Teaching) Methods

The content of a subject determines what method to be used to achieve effectiveness in the teaching and learning process. Subjects definitely require different teaching methods that suit such disciplines. Computing can be also taught with inquiry or discovery methods, while the lecture method can be used in some art subjects depending on the specific content of the particular subject.

The instructional objectives a teacher intends to achieve at the end of a lesson determine the choice of teaching method to use in teaching the subject.

The four cornerstones of the decision-making field described in Fig. 7 are ideal-typical exaggerations of the repertoire of teaching methods. They represent fundamental perspectives. They are not models for planning and designing real lessons. Such models are multifaceted modifications and additions of the four basic patterns:

An exclusively instructive lesson is just as unthinkable in school reality as a purely discovering lesson in completely teacher-directed lessons is, apart from special situations, as unrealistic as completely autonomous learning. The reality of effective teaching lies between the four cornerstones of the methods.

Every well-founded lesson preparation requires guidance by the teacher, even if a more autonomously discovering lesson method is pursued. No teaching model can be classified unambiguously in the context of the decision-making field. This applies above all to methods that work in a longer time horizon: Within the framework of a project or a didactic work, guided or autonomous elements can be used, depending on the topic.

The teaching of student groups requires decisions in order to determine the most meaningful social form for the different teaching phases.

The realization of an effective lesson requires a high degree of flexibility in order to be able to respond to the constantly changing conditions of a school lesson. In addition to the necessary pedagogical skills, one needs the knowledge to master special “critical” situations, as they are typically associated with the respective teaching methods.

The best teaching method is the one that your students respond to. Good teachers adjust their methods in response to their pupils’ ability to learn the material being presented. Good direct instruction is still a very effective method especially when working in introductory courses.

The following suggestions are made for effective use of teaching methods in the teaching and learning process:

**Computing Education,
Practices in, Fig. 7** Basic
patterns

1. Teachers should know the nature of the subject matter to be taught and be conversant with it to enable him/her to determine the most suitable teaching method/methods to use in a given lesson.
2. The instructional objectives a teacher intends to achieve by the end of the lesson determine to an extent the type of teaching methods. Teachers should try to match the instructional objectives to suit the teaching methods to be chosen for a lesson.
3. The teacher must be very familiar with the type of teaching methods he/she wants to use at any given time and must ensure it is most appropriate for the success of the lesson.
4. The teacher must consider the age, interest, etc. of the learner and ensures the right teaching methods and materials that will suit the learners are in place.
5. In choosing appropriate teaching methods, the teacher is encouraged to consider the time to be used for a lesson, as this will go a long way to determine also the type of teaching methods to use.
6. The teacher should put into consideration the population of the class, the environment, and the size of the class. This will help to determine

a most suitable teaching method to use for a lesson and make it worthwhile.

Within the plethora of teaching methods, there are some which meet the requirements of computing lessons better than others.

Task- and Problem-Based Learning

One approach to plan a scheme of work for computing lessons is centered about tasks and problems.

Task-based learning is a teaching method for short lesson sequences. Already covered and understood subject matter and solved tasks can be deepened by extended tasks.

One special type of tasks is so-called Beaver tasks which are the constituent part of the Online Bebras Contest which takes place every year in over 50 countries worldwide (2018), reaching almost 3 million pupils. These short tasks, each of them with a strong, but for many pupils hidden, computing background, can be solved “unplugged” through (computational) thinking (Dagiene and Stupuriene 2014).

Since 2014 more than one thousand Beaver tasks are publicly available and can be used as starting points for many computing activities (Fig. 8).

**Computing Education,
Practices in,**
Fig. 8 Digital broken
clock

On a digital clock, each digit can be formed by lighting up some of the seven segments.

Below, each of the digits from 0-9 are shown by lighting up some of those seven segments.

What is the largest possible number of segments that are not working.
0, 1, 2 or 3?

Beaver tasks are computational puzzles and therefore ideally suited for activating the brain, looking for solutions by logical reasoning and associative thinking, and having fun in case of finding the correct result.

Computer Science Unplugged activities (also known as CS Unplugged) are a problem-based approach without requiring students to use a computer (Bell and Newton 2013). An impressive example is the “parity trick,” which is presented as a magic trick, based on the concept of error-correcting codes (Fig. 9).

Problem-based approaches structure students’ activities more by asking them to solve specific (open-ended) problems rather than relying on students to come up with their own problems in the course of completing a project, an approach which is the prerequisite of project-based learning.

Another seemingly similar approach is quest-based learning; unlike project-based learning, in questing, the project is determined specifically on what students find compelling (with guidance as needed), instead of the teacher being primarily responsible for tasks.

Discovery or Inquiry-Based Learning

This approach of learning is a vaguely defined generic term for several methodological

variations according to the degree of the teacher’s involvement. In structured and guided inquiry-based learning, the teacher provides the pupils with methods, tools, and materials. The pupils should discover and develop their own approaches and problem-solving methods as independently as possible or as part of a team. In (totally) open discovery learning, the teacher withdraws almost entirely. The pupils find their own research topic themselves and work on it independently.

Inquiry-based learning is basically a pedagogical method, developed during the discovery learning movement of the 1960s as a response to traditional forms of instruction where people were required to memorize information from instructional materials, such as direct instruction and rote learning. The philosophy of inquiry-based learning is deeply rooted in constructivist learning theories, such as the work of Dewey (1997).

Learning by Doing

Action-oriented teaching in form of physical computing and robotics within the worldwide Maker Movement is still gaining pace in computing education, although not part of everyday computing yet. Research shows that this approach is very popular among pupils (Bartel 2000). Among

Computing Education, Practices in, Fig. 9 Unplugged parity trick (open house day in an Austrian school)

about many other teaching methods and approaches, “devising practically functioning” ranks in the first place, leaving methods as group work, learning by teaching, pair programming, and discovery learning behind.

Media and Tools

Talking and writing about practices of computing education and not mentioning at least some of digital software tools and digital devices, used in computing lessons, would be a gross negligence. All abovementioned learning theories can be assigned to digitally and technologically enhance computing learning. It is evident that the vast majority of everyday computing lessons do make (heavy) use of informatics systems and digital devices (hardware in different forms), learning platforms, standard and development software, as well as social media, assessment tools, and open educational resources (Passey 2015; Anderson 2013).

Time and Room

The time allotted to a subject on the school timetable must be taken into account when determining the choice of teaching method. Time-consuming methods like the abovementioned group puzzle, role-playing, station learning, or complex simulations can be done within double periods. When there is little time to execute a considerable scheme of work, then direct instruction is appropriate, having the mental capacity of learners in view.

Especially in computing lessons, the classroom environment can have a great influence on students’ performances and outcomes. Classroom layouts in computing classrooms (computer labs) need to be carefully designed considering having separate tables in the middle of the room for planning and theory work.

Classroom environments set a tone for learning and cause learners to behave in certain ways. It is important to consider the classroom environment in selecting an appropriate teaching method for a lesson. The space available in a class, ventilation, illumination, and other teaching devices in a classroom, etc. all these affect the choice of teaching methods to be used.

Concluding Remarks

Practices in computing education in schools and formal settings in classes and classrooms comply with the same conditions, habits, and routines as in other subjects. Accordingly, successful computing education depends also on good classroom culture and behavior management, on a sound lesson pace and differentiation, and not least on appropriate assessment methods, marking, and feedback strategies.

Control Technology and School Curricula in the Late 1980s in Australia

Arthur Tatnall
Victoria University, Melbourne, VIC, Australia

Synonyms

Machine control; Mechanized systems; Robots

Introduction

The term **Control Technology** can be defined as “an application involving the use of a computer, with the aid of suitable interfacing and software, to give its user control of some external process” (Tatnall and Tatnall 1987). Examples of control technology include devices such as robot vehicles and “turtles” (The Turtle was an early robot used in education by Seymour Papert), robot arms, industrial robots, equipment to monitor and control scientific experiments, process control equipment, computer numerically controlled lathes, and other automated machines (Tatnall 1990).

Although there had been some examples of control technology in schools before this, in some schools in Australia, it began to be treated seriously as an addition to secondary school curricula in the mid-late 1980s, and in primary schools a few years later. Although not many schools made use of control technology at the time, it was generally recognized that an understanding of the principles of machine control and how technology actually works, of what robots could and could not do, and why they were being introduced in factories should be an important and relevant part of secondary education. The first question that was asked by educators, though, concerned the benefits that learning about (and with) this material would be to students. The question then became, at what school levels did the *content* of a course on control technology become important, rather than just *use* of this technology in the process of problem solving? (Tatnall and Davey 1986). One practical concern was the extent to which many teachers felt comfortable in using this technology.

Mechanized Systems

In studying mechanized systems, three fundamental elements need to be considered: power, action, and control. The first two belong to the realm of mechanical engineering, but control is related closely to computing. We can consider several levels of control: uncontrollable, operating under

human control, using automatic control and involving full automation. Control technology is concerned with automatic control and with full automation. A device cannot properly be considered to be a robot unless it is automated and can be programmed to perform more than just a single task. Hence, robotics is a hybrid of mechanical engineering and computer science. The term *robot* comes from “Rossum’s Universal Robots,” a 1920 play by Karel Čapek (1920) and *robotics* or the study of the use of robots was popularized in the 1950s by the science fiction writer Isaac Asimov (1950).

Control Technology Learning Materials: Late 1980s and Early 1990s

While not a complete list of those technologies available at the time, some of the most useful materials for senior secondary school courses in control technology were:

- LEGO Technic Control and LEGO Logo. This consisted of LEGO bricks, the LEGO manual control unit, LEGO control interface, interface cards appropriate for a variety of microcomputers available at the time (including Apple // e, BBC, Commodore 64 and IBM-PC (compatible) computers), software, and instructional materials. LEGO Lines and LEGO Logo programming languages were available (Carter 1988; Harvey 1985; LEGO 2018).
- Fischertechnik Robotic Computing Kits. Like LEGO, these contained building bricks, interfaces, software, and instructional materials and could be used with available microcomputers (Fischertechnik 2018).
- The Tasman Turtle. This LOGO-based educational robot had speech recognition and synthesis, electronic compass, touch sensors, drawing pen, motion control, and an infrared interface (Denning Branch International 2005).
- Trekker Robot Vehicle (from Clwyd Technics, Wales). Trekker was a completely built-up robot vehicle very well equipped with touch,

magnetic, ambient light discrimination, and contrast light discrimination sensors (Centre for Computing History 2018).

- Special devices such as robot arms, computer numerically controlled (CNC) lathes, and equipment for measurement and monitoring of scientific experiments.

Teachers reported that some of these technologies were, however, more difficult to make use of than others.

Educational Elements of Control Technology

As control technology systems began to be used in some schools, they were considered to consist of five educational elements:

1. Design and problem solving. This would involve selection of an appropriate project, collection of information, deciding how to go about constructing a solution and the actual design of this solution. This was an important first step.
2. Building the model to be machine controlled. The physical construction of the model – the engineering, comes next. This aspect of control technology is perhaps not as important with older students as with younger, but was still a part of the process.
3. Interfacing the model to the computer. While making the actual connections of the motors, lights, and sensors could be considered as part of the construction, this was better thought of as a distinct element involving different skills.
4. Use of sensors and feedback mechanisms. While not all models needed to include use of sensors, these sophisticated concepts were introduced in some secondary schools.
5. Programming. It is in control programming that computer science came in. Particularly at the senior school level, the writing of control programs was seen as the most important aspect of all, and as the culmination of the whole process.

Controlling a Robot: Control Programming

Controlling a robot is an essential aspect of robotics, and robots need to be programmed in order to perform their tasks. In principle, any programming language that can control the computer's input and output lines could be used to program a robot. At the robot-end, the programming consists of switching particular control lines on and off (to control robot motors), and checking whether other lines are registering a value or not (robot sensors). At the computer-end, a high-level programming language is used, which is translated into these on and off signals. In practice in the late 1980s and early 1990s, some programming languages proved more suitable for robot control than languages like Pascal or BASIC that were then used in many schools. FORTH and LOGO were useful in this context as were specialized robot programming languages such as VAL, WAVE, LM, SIGLA, and EMILY, although use of these specialized languages was not at all common in schools.

In the choice of which programming language to use, an early decision was first necessary on why the students were studying control technology. To what extent were they concerned just with controlling the device, compared to understanding how that control is achieved and delivered? If the answer was that they were more concerned with the problem-solving aspect and with controlling the device, but did not want to get involved in the actual bits and bytes, then LEGO Logo was undoubtedly the best programming language to adopt. At the other extreme, secondary school computer science courses that wanted to show the students something of interfacing, the use of a low-level programming language was found useful, but this was used only in a small number of cases.

Curriculum Possibilities Involving Use of Control Technology

Control Technology was one of the very earliest applications for microcomputers in education. At

the start of computer education in the late 1970s – long before the concept of LEGO Logo was born, a number of enthusiastic Australian teachers were interfacing their computers to all sorts of external devices. This tradition continued, and teachers with these interests continued to do incredible things with very little resources. Such activities were, however, not the norm.

Courses in control technology in some schools (particularly secondary and technical schools) were made up from many of the following elements:

- Problem solving and computing concepts
- Electronics – chips, analogue to digital conversion
- Interfacing – memory locations, data transfer
- Mechanics – motors, gears, and pneumatics
- Cybernetics – control systems
- Control programming – high and low-level
- Science – sensors, feedback, monitoring, and control
- Mathematics – design and geometry of robot arms
- History of mechanization and robotics
- English – robots in fiction
- Social science – robots and people
- Economics – the commercial imperative

Problem Solving and Computing Concepts

It is easy to see how computing concepts could be taught through a control technology course. Problem solving is essential and programming becomes very real when it causes a robot to move under your command! High level instructions could be written in Logo or another suitable control language and low-level instructions and monitor codes could also be investigated (Tatnall and Davey 1985, 1990).

Electronics and Interfacing

Control technology is based on the use of electronics, and while not many school wanted to dip into this some schools, particularly technical schools, did.

Science: Sensors, Feedback, Monitoring and Control

Robot control requires feedback of the exact whereabouts and condition of the robot's parts. Before a robot welder could begin welding, its controller needed to be sure that the tool was in the correct place and that the metal to be welded was also in place. Monitoring and control of science experiments was an important use of control technology, and students could make use of experimental apparatus equipped with sensors to take predesigned actions.

Mathematics: Geometry of the Robot Manipulator Arm

A good deal of mathematics is involved in the design of an industrial robot's manipulator arm. Like human limbs, robot arms are jointed. Unlike human joints, where only rotation is possible, two basic kinds of motion are possible at a robot arm joint: rotation and sliding. A jointed arm is characterized by its number of "degrees of freedom." In the simplest case, a machine has as many degrees of freedom as it has joints. Students at upper secondary and technical schools were encouraged to build models of Cartesian, polar, cylindrical, horizontally-jointed, vertically-jointed or anthropomorphic arms, and to study the mathematics involved in controlling each (Smith 1986).

English: Robots in Science Fiction

Robots in fiction are usually either very good or very bad; they are seldom just machines. A useful addition to the curriculum undertaken in some schools at all levels was to discuss this and to attempt to relate it to our conception of machines. The novel "Frankenstein," written by Shelly (1818), popularized the idea of a "non-human" monster. Although Frankenstein's monster was not a robot, the popular idea of a robot owes a lot to this novel. Many books and films have used robots in their plots and a good deal of interesting material can be found in the study of these. Apart from the classic "I Robot" and R. Daneel science

fiction series by Isaac Asimov (1950), there was Marvin the paranoid android in Douglas Adams' "Hitch Hiker's Guide to the Galaxy" (Adams 1979), as well as C3PO and R2D2 from Star Wars, and K9 and the Daleks from Dr. Who. Even junior primary school students had heard of, and wondered about, many of these robots.

Social Science: Robots and People

In the play "Rossum's Universal Robots" the author has Rossum say:

A man is something that feels happy, plays the piano, likes going for a walk, and, in fact, wants to do a whole lot of things that are really unnecessary ... But a working machine must not play the piano must not feel happy, must not do a whole lot of other things. Everything that doesn't contribute directly to the progress of work should be eliminated. (Čapek 1920)

This play was written about 70 years ago and paints a very pessimistic picture of robots and humans. Isaac Asimov, who did more to popularize the idea of robots, had a much more optimistic view, which he expressed in his many science fiction books.

Issues of the place of robotics in our society were seen as a fruitful study for senior secondary school students undertaking courses in Information Technology. There was plenty of material in the press, in books, and in magazines to support this study. The issue of what work robots *should* do had, even then, been under considerable debate for some time and to what extent they should be allowed to displace humans. This made a useful source of discussion and debate in secondary school English classes (Groves 1985).

Issues such as the problem of designing a guard-robot to patrol a factory at night in place of the night watchman were discussed. There were seen to be plenty of questions that students could research and discuss in this scenario. Questions such as: With what type of sensors would the robot be equipped? How would it move about? Should it be armed? What action should it take on discovering an intruder?

Economics

Industrial robots and control technology can be regarded as a replacement of the need to use human workers. While installing a robot does not necessarily mean sacking a worker, the industrial robot nevertheless acts the part of a worker. Most of the reasons industry needs to use robots are based on economics. Several Melbourne technical schools were linking control technology and economics in a novel manner. They were using CNC (Computer Numerically Controlled lathes) lathes to manufacture small items such as tow-balls for car trailers. Initially the teacher showed the students how to program the lathe to cut the tow-balls. Next the students were given the task of deciding on the price for which the tow-balls could be sold. This needed to take into account the cost of materials and the cost of using the lathe (based on construction time). The students then actually went into the business of selling the tow-balls. In the next stage, they tried to improve the efficiency of the process. Could the cutting program be improved so that the process could be performed more quickly, hence reducing lathe costs? Could it make more efficient use of the materials and so reduce waste?

Some Control Technology Projects

Any number of projects could be designed for year 11 and 12 students (Aged around 16–18) to build, particularly using Lego Technics, but some of those used in primary and secondary schools in Melbourne included:

1. **Maze solver.** Students at senior primary schools were asked to design a simple maze with one exit, and build it from cardboard or wood. Their LEGO robot vehicle would then need to be programmed to find its way out of the maze.
2. **Robot arm.** This was a more complex project used in some secondary schools and involved

students in building and testing a computer-controlled robot arm.

3. **Automated Conveyor Belt.** A less complex project involved building a conveyor belt that could automatically sort large Lego bricks from small bricks. Later this could be improved to sort light-colored bricks from dark-colored bricks.
4. **The robot “animal”.** In this quite complex project, students tried to build a robot vehicle that exhibited (pseudo) animal behavior such as shrieking when touched, grazing only on green grass (paper), avoiding hazardous materials, running away from bright lights, stopping when a shadow passed over it, stopping at the edge of a cliff, and patrolling its own territory.
5. **Mars explorer.** In another project, students were to design a robot to explore the Moon, Mars or another planet. It would need to be able to move around freely, to be well equipped with sensors, and to be able to transmit information from its sensors back to Earth.

Difficulties Found in Introducing Control Technology Courses

Times changed and new materials became available. By 1990, LEGO Technic materials had been readily available for several years, so why were they not being used in all schools?

There were several problems in the adoption of control technology materials in information technology courses. Firstly, there were, for many teachers, the difficulties of electric wires, power supplies, and connections to a computer, and many teachers stepped back in horror at the idea of all that this involved. Then there were the logistics of keeping track of all the small LEGO materials.

Next, there was the problem of the significant learning threshold (on the part of the students and the teacher) before anything useful could be done with control technology materials. Certainly, most people found that building the LEGO models was quite easy, but some teachers found that also having to learn to write control programs was a bit daunting. While these materials were not really

very difficult to use, there was a perception among busy teachers that their use would involve a lot of preparation work. The task of designing such curricula at the school level was a time consuming one, and one more impediment to the widespread use of control technology. The problem of cost was also not insignificant, as the purchase of the LEGO materials, suitable interfaces, software, and computers involved quite a lot of money. For many schools, particularly primary schools, obtaining sufficient funds to buy enough of these materials for class use was very difficult.

Conclusion

The term *robot* has always held some fascination with school students, particularly after seeing the humanoid variety in many science fiction films and comics. The thought of being able to construct your own robot (or some aspects of it) was instantly appealing in the 1980s (and also today). Despite the implementation difficulties involved, the educational benefits of including Control Technology units in Information Technology school subjects began to become clear to see in the late 1980s, although not all schools took advantage of this. Students though thought it fun and were enthusiastic about its use. Teachers were then beginning to realize that such technology related well to the outside world, was a good vehicle for practice in problem solving, and was worth learning about.

Creative Commons

While it might sound encouraging to believe that “information wants to be free,” this mantra often represents a misguided belief that intellectual property rights have no place in modern society. In fact, this is actually quite far from what Stuart Brand likely meant when he purportedly said this to Steve Wozniak in 1984. What Brand probably meant was that technological constraints placed on information (text, images, code, audio, video, etc.) are by default arbitrary add-ons put in place after the fact – after the initial creation of the item in question – and are therefore arbitrary and typically counterproductive to the widespread diffusion and use of these items. That is, the default state of information is free in terms of

accessibility. Locking it down by way of digital rights management (DRM) systems and platforms to protect the intellectual property rights of the respective creator(s) always requires additional measures to do so. While anthropomorphizing information as having distinct “wants” of course does not make any literal sense, since information itself cannot “want” anything, the initial, default state of all information is free until otherwise changed.

Richard Stallman, founder of the Free Software Foundation and the GNU General Public License, would later add to this idea by making the distinction one between “free” and “freedom”, respectively. Lessig himself attempts to qualify this difference when he stated that “‘Free’ has different senses, only one of which refers to ‘price’.” Lessig further adds that “A much more fundamental sense of ‘free’ is the ‘free’... in the term ‘free speech’ or perhaps better in the term ‘free labor’. Not free as in costless, but free as in limited in its control by others” (Stallman 2002).

Stallman believes that “generally useful” information should be available for adoption and/or adaptation as needed. He does not attempt to stipulate a definition to frame exactly what he means by “generally useful,” so the term itself is subject to wide interpretation. That being said, after the initial creation of such “generally useful” information takes place, what then should be done with it to disseminate and/or otherwise promote it to the world or some narrow slice thereof? This is what Lessig, Abelson, Eldred, and Plotkin attempt to address with their collaborative brainchild, Creative Commons.

As the name implies, Creative Commons represents a middle ground in the intellectual property ecosystem – a step somewhere between public domain (no rights reserved) and copyright (all rights reserved). Lessig and the other co-founders based Creative Commons around a series of licenses creators can choose for content they create. The licenses are written in both legally binding and plain English text, to serve both content producers and content consumers.

These licenses can be easily applied to any content by way of simple, online forms, and the licenses can be customized as needed by the

content producers. The end result is a middle ground between the public domain and copyright, designed so creators can metaphorically “free” their creative works for greater diffusion into society, for the common good.

This middle ground is not a static, “one size fits all” approach but is instead a sliding scale, allowing more or less control based on the desires of the individual content producer, in order to help “clarify the rules of creativity” (Reticulum Rex 2003). These licenses ultimately provide content producers with a means to “...retain copyright while allowing others to copy, distribute, and make some uses of their work” at the discretion of the content producer. Additionally, every Creative Commons license ensures the following:

1. The content producers in question (referred to as “licensors” in Creative Commons documentation) get the credit for their work they deserve.
2. The licenses are applicable and enforceable worldwide, “...because they are built on copyright” (Creative Commons, About the Licenses).

This theme of “enforceable credit” is a central tenant to all of their licenses. The primary Creative Commons licenses are as follows, with some offshoots and variations made in the past decade (About the Licenses 2017):

- **Attribution** (CC BY) – This license allows distributing and/or modifying work, as long as credit is given to the original content producer.
- **Attribution-ShareAlike** (CC BY-SA) – This license allows distributing and modifying work, as long as credit is given to the original content producer. The new, modified work must be licensed the same way.
- **Attribution-NoDerivs** (CC BY-ND) – This license allows distributing the work unchanged, commercially or noncommercially, as long as credit is given to the original content producer.
- **Attribution-NonCommercial** (CC BY-NC) – This license allows distributing and modifying work noncommercially, as long as credit is given to the original content producer. The

new, modified work does *not* need to be licensed the same way.

- **Attribution-NonCommercial-ShareAlike** (CC BY-NC-SA) – This license allows distributing and modifying work noncommercially, as long as credit is given to the original content producer. The new, modified work *must* be licensed the same way.
- **Attribution-NonCommercial-NoDerivs** (CC BY-NC-ND) – This license allows distributing work unchanged, noncommercially only, as long as credit is given to the original content producer.

Each license has its own icon associated it with that links to additional legal and machine-readable information as in Fig. 1.

In many respects, the Creative Commons licenses represent a metaphorical extension of the GNU General Public License and the notion of “copyleft”, developed by Stallman several years prior. Stallman’s goal with the GNU General Public License was also to have a middle ground between the public domain and copyright, yet for different reasons. His intention was to make absolutely certain that programmers who wished to release their code for free could ensure that it

remained so permanently. If their code was only made available in the public domain, anyone could freely use it and modify it as needed, but they could also modify it and then copyright it – effectively forking it, thereby closing it off from further modifications and free use. “If middlemen could strip off the freedom,” Stallman argues, “we might have many users, but those users would not have freedom” (Stallman 2002).

The method of “copylefting” a program involves stating that the code in question is copyrighted, then “. . . we add distribution terms, which are a legal instrument that gives everyone the right to use, modify, and redistribute the program’s code or any program derived from it but only if the distribution terms are unchanged.” Taking this approach, Stallman asserts, makes “the code and freedoms . . . legally inseparable” (Stallman 2002). The GNU General Public License most closely matches the Creative Commons Attribution-NonCommercial-ShareAlike license, though there are still several minor differences.

Depending on the context and specific needs of the respective content producer(s), any of these licenses – of course including the GNU General Public License – may be relevant. If

Creative Commons, Fig. 1 Creative Commons licenses. (Note: image free for commercial use; no attribution required)

photographers want to make collections of their images available royalty-free, for example, they could choose to do so under an “attribution-only” Creative Commons license, which requires users to essentially give creative credit where such credit is due. These same photographers could also release their work under an “attribution-only/noncommercial” license, which would still make such content available royalty-free, but only for personal, noncommercial use.

The ties between Creative Commons and social media are simultaneously obvious and tenuous. While not specifically targeted at growing any individual social media platform or services, Creative Commons-licensed works have no doubt played a role in a broader sense of the term. A central premise of Creative Commons is that, historically, creativity has always been built upon the past work of others and that the “full potential of the Internet” can best be realized by unleashing the full potential of creative works as content producers see fit to share them (Building on the Past 2003). As of this writing, Creative Commons now claims over 1.2 billion licensed

works in various formats (State of the Commons 2017), to “. . . help authors and artists build a body of free culture they can draw from in return.” This represents a sizable growth trajectory given that it started with roughly 100,000 licensed works in 2001 (Reticulum Rex 2003).

So, while Creative Commons cannot be directly tied to the growth of Facebook, Instagram, Twitter, Tumblr, SoundCloud, Flipboard, and other social media platforms, Creative Commons has still perhaps indirectly aided in their broader use. If anything, Creative Commons itself can perhaps be seen as a separate, parallel social media platform that can overlap with any of the platforms listed above. There is certainly no shortage of examples of Creative Commons-licensed images available on Instagram or Flickr, for example, as well as Creative Commons-licensed audio files on SoundCloud. Searching for Creative Commons-licensed content is equally easy in these and other platforms (Fig. 2).

The impact of Creative Commons has had and continues to have on these platforms is perhaps

Creative Commons, Fig. 2 Creative Commons search tools using Bing

Creative Commons, Fig. 3 Creative Commons image search, Flickr

less relevant than the broader use and acceptance of Creative Commons, in general. In terms of the relationship to Creative Commons, these social media platforms really just represent a series of delivery methods content producers can use to deliver and disseminate their works to others. They are not the end game unto themselves toward this end but rather a means to an end to further the act of sharing and creativity (Figs. 3 and 4).

The same could be said in industries where Creative Commons might initially seem antithetical, such as academic publishing. The open-access movement for academic publishing, for example, might never have become as widely diffused and accepted as it is now without the ability for authors to use Creative Commons licenses. The Science Commons project of Creative Commons has served as a key player in helping foster and promote Open Educational Resources (OER) worldwide. Similar initiatives,

including the Berklee Shares project, MIT Open Courseware, and a host of other efforts, would likely not even exist without Lessig and others initially having paved the way with Creative Commons (Berklee Shares 2017).

Many academic publishers now include options for authors to release their works under Creative Commons licenses. Elsevier, for example, offers authors "...a choice between a commercial and a noncommercial Creative Commons license for gold open access articles" in numerous journals (Elsevier Open Access Licenses 2017). The specific licenses used are the Attribution 4.0 (abbreviated as the CC BY) and the Attribution-Noncommercial-No Derivatives (abbreviated as the CC BY-NC-ND) (User Licenses Offered by Elsevier 2017). Given the size and stature Elsevier commands in academic publishing, this represents a huge new avenue for authors who want their works to become as broadly disseminated as possible.

Creative Commons, Fig. 4 Creative Commons audio search, SoundCloud

Louis Suarez-Potts, longtime open source advocate and former community manager of the OpenOffice projects, agrees. When discussing open source initiatives and related alternatives to traditional copyright at the University of Buffalo, he argued that such efforts work “. . . regardless of the motivator; and motivators beyond price work even in closed source environments. What counts, then, is engaging people so that the value of their actions and role goes beyond price” (Lim 2009). Kembrew McCleod echoes this sentiment. He asserts in his increasingly relevant text, *Freedom of Expression*, “the ability to record, comment on, and distribute media content is essential for the survival of a robust democracy and the cultivation of a free culture in the information age” (McCleod 2007). While McCleod primarily meant this in reference to traditional notions of fair use, his views still echo the importance of what the Creative Commons initiative has been all about and what works have been developed as a direct result of this effort.

Information may not want to be free, but content producers may want the option of making it so. Even high-profile skeptics of alternative copyright solutions like Bill Gates, who once famously derided those promoting such efforts as being “. . . new, modern-day sort of communists” (Andrews 2005), have come around. The Bill & Melinda Gates Foundation now *mandates* that all funded research projects be published under the Creative Commons Attribution 4.0

generic license or equivalent. The foundation leadership took this once unthinkable step to promote “. . . The free, immediate, and unrestricted access to research will accelerate innovation, helping to reduce global inequity and empower the world’s poorest people to transform their own lives” (Gates Foundation, Open Access Policy).

There are 1.2 billion reasons why Creative Commons works and how this effort has helped disseminate knowledge and creative works worldwide. Let us hope there will soon be 1.2 billion more reasons in the coming years.

Curricula in Computer Science

Mary E. Webb

King's College London, London, UK

Introduction

In recent years, a number of reports from various countries have expressed concerns about Computer Science being neglected and school curricula not serving learners' or their countries' needs well (Joint Informatics Europe and ACM Europe Working Group on Informatics Education 2013; The Royal Society 2012; Wilson et al. 2010). Subsequently many countries have reviewed their curricula and in some cases brought in major reforms that focus on incorporating more Computer Science (Webb et al. 2017). This article aims to review concerns and recent changes and to examine their rationale. Furthermore, the article discusses the challenges associated with achieving a curriculum, incorporating Computer Science, that is fit for purpose. First key terminology in relation to Computer Science curricula is defined since variations in the use of terminology can be a source of confusion.

Terminology and Definitions

When discussing curricula for Computer Science, the need to identify an acceptable working definition for Computer Science as a curriculum subject is a key consideration. Some popular definitions (Fluck et al. 2016) are:

1. It seeks to answer the following questions: What is information? What is computation? How does computation expand what we know? How does computation limit what we can know (Denning 2007)?
2. The study of computers and algorithmic processes, including their principles, their hardware and software designs, their implementation, and their impact on society (ACM 2003).

3. The scientific and practical approach to computation and its applications and the systematic study of the feasibility, structure, expression, and mechanization of the methodical procedures (or algorithms) that underlie the acquisition, representation, processing, storage, and communication of and access to information (https://en.wikipedia.org/wiki/Computer_science).

In addition, definitions based on areas of knowledge can be found through widely adopted curricula, such as the ACM/IEEE Computer Science curriculum for undergraduates (Sahami et al. 2013). The *Wikipedia* definition (https://en.wikipedia.org/wiki/Computer_science) gives a clear overview and reflects recent consensus on the general nature of Computer Science as well as current practice, so the *Wikipedia* definition will be used throughout this article.

This article uses the term, Computer Science, for the curriculum subject, and this is in line with a number of countries and organizations, including the influential US-based “Computer Science Teachers Association” that has developed a set of standards for Computers Science (<https://www.csteachers.org/page/standards>). However, the name used for the curriculum subject varies across different countries. For example, Informatics is slightly broader than Computer Science but is the term used widely across Europe to refer to this discipline. For example, the Joint Informatics Europe and ACM Europe Working Group on Informatics Education use the term Informatics to “cover the entire set of scientific concepts that make information technology possible” (Joint Informatics Europe and ACM Europe Working Group on Informatics Education 2013, p. 9).

Another key term that is central to many recent curricula for Computer Science is Computational Thinking, an approach to problem-solving conceived by Seymour Papert (1996) and recently re-emphasized by Jeannette Wing (2006). Overall, Computational Thinking is about analyzing and solving problems and presenting solutions in such a way that they can be

implemented on computers. Therefore, Computational Thinking draws on fundamental concepts and techniques from Computer Science such as abstraction, decomposition, pattern recognition, and algorithm design. Computational Thinking, according to Wing, may be regarded as a fundamental skill set, for the digital age, alongside literacy and numeracy; therefore the position of Computational Thinking in the curriculum has become the subject of some debate. The diagram in Fig. 1, based on (Webb et al.), shows Computational Thinking, developed in Computer Science but snaking across the curriculum, where students use Computational Thinking processes or elements of Computational Thinking to support their learning of other subjects as well as to develop their experience of the ubiquity and importance of Computational Thinking.

Concerns About Computer Science in the Curriculum

The focus of the major reports that highlighted concerns about Computer Science (Joint Informatics Europe and ACM Europe Working Group on Informatics Education 2013; The Royal Society 2012; Wilson et al. 2010) was that the academic curriculum subject, Computer Science, had been lost from school curricula as a result of a too limited focus on developing only basic digital literacy. Basic digital literacy is important as it can enable students to use business applications, such as databases and spreadsheets, as well as understand and use Internet-based resources ethically and safely. However, typically digital literacy does not provide students with the understanding together with technical and creative skills to enable them to innovate with technology and thus contribute to the development of economies and society. Therefore, all of the reports (Joint Informatics Europe and ACM Europe Working Group on Informatics Education 2013; The Royal Society 2012; Wilson et al. 2010) advocated the need for both digital

Curricula in Computer Science, Fig. 1 Computing-related terms in relation to the conventional school curriculum

literacy and Computer Science in school curricula. Subsequently, in many countries, new curricula have been developed that incorporate Computer Science (Webb et al. 2017), typically throughout compulsory education (see, e.g., <https://www.csteachers.org/page/standards>; <https://www.australiancurriculum.edu.au/f-10-curriculum/technologies/>; Department for Education 2013; Ministry of Education New Zealand 2017).

Defining the Scope of a Curriculum

An analysis of developments in five countries as well as a review and content analysis of curriculum reports (Webb et al. 2017) suggested key issues to consider when designing Computer Science curricula. First there is a consensus (see Table 1) across curriculum reports about the key concepts and techniques of the discipline (Webb et al. 2017). However, there is as yet no consensus about the importance of more general intellectual practices such as persistence in working through problems and tolerance for ambiguity as well as the importance of collaborative learning and social competence developed

through group work that were emphasized by the European report (Joint Informatics Europe and ACM Europe Working Group on Informatics Education 2013).

Thus, the recent curriculum design, incorporating Computer Science, has achieved the goal of defining “powerful knowledge,” i.e., specialized discipline-based knowledge, which is an entitlement for learners (Young 2013). As Young (2013) argued, “powerful knowledge,” although constantly changing, can be determined by subject experts, and this is typically how the content of these curricula has been specified. A challenge remains to ensure the currency of curricula. For example, in defining curricula for undergraduates, a key challenge discussed by the ACM/IEEE was to maintain the curriculum within an acceptable size given the rapid developments in the field, so the focus is on identifying new topics that merit incorporation and continuing to evaluate the importance of existing topics (Sahami et al. 2013). For secondary schools, it is also important to maintain the currency of the curriculum, in order both to provide a sound basis for future study and to promote students’ motivation by enabling them to understand the relevance of what they are studying. As shown in Table 1,

Curricula in Computer Science, Table 1 Analysis of key areas of knowledge of Computer Science in curriculum reports. (Adapted from Webb et al. 2017, p. 459)

	Computer Science Teachers Association (CSTA) curriculum standards (http://www.csteachers.org/page/standards)	Royal Society report (The Royal Society 2012)	Joint Informatics Europe and ACM Europe Working Group (Joint Informatics Europe and ACM Europe Working Group on Informatics Education 2013)
Overview of “discipline” of Computer Science/ Informatics and foundational principles	The study of computers and algorithmic processes, including their principles, their hardware and software designs, their implementation, and their impact on society (ACM 2003)	Encompasses foundational principles, widely applicable ideas and concepts, as well as techniques and methods for solving problems and advancing knowledge as well as a distinct way of thinking and working (page 19)	Informatics is a distinct science, characterized by its own concepts, methods, body of knowledge, and open issues (page 3).
Key areas of conceptual knowledge	Strands are data and analysis, algorithms and programming, impacts of computing, computing systems, networks and the Internet computational thinking, collaboration, computing practice, computers and communication devices, and community, global, and ethical impacts	Programs, algorithms, data structures, architecture, and communication	Provides the following as examples from a long list of concepts: algorithm, performance and complexity, data structure, concurrency (parallelism) and distribution, language (including programming languages), abstraction
Techniques and methods	A wide range including techniques and methods for analyzing massive data, solving problems, authentication, recursion, object-oriented modelling, search, testing, and refinement	Computer Science “methods” or ways of thinking include: • Modelling: representing chosen aspects of a real-world situation in a computer • Decomposing problems into sub-problems and decomposing data into its components • Generalizing particular cases of algorithm or data into a more general-purpose, reusable version • Designing, writing, testing, explaining, and debugging programs (page 20)	Problem-solving techniques include: • Representing information through abstractions • Logically structuring and analyzing data • Automating solutions through algorithmic thinking • Identifying, analyzing, and implementing possible solutions with the goal of achieving the most efficient solution • Formulating problems in a way that facilitates the use of a computer • Generalizing (page 12/13)
Ways of thinking and working	Practices include communicating, testing, abstraction, creating, solving computational problems, collaborating	Computational thinking Logical thinking Systematic thinking Analytical thinking	Intellectual practices include: • Confidence in dealing with complexity • Persistence in working with difficult problems • Tolerance for ambiguity • Ability to deal with open-ended problems • Ability to deal with a mix of both human and technical aspects • Ability to communicate and work with others to achieve a common goal or solution (page 13)

there is currently a consensus over key areas of conceptual knowledge, but at a more detailed level, there can be a long list of concepts (Joint Informatics Europe and ACM Europe Working Group on Informatics Education 2013). Furthermore, even some of the standard curriculum content may be brought into question by future curriculum content based on new technological developments, for example, quantum computers that operate on completely different principles (Fluck et al. 2016). In summary, there is consensus regarding key concepts and techniques crucial for Computer Science in the school curriculum. However, the structure of the curriculum and the appropriate age for introduction remain challenging as discussed next.

Structure of the Curriculum

Ideally the structure of a curriculum would be determined by detailed evidence of learners' progression in understanding. For example, in some subjects such as mathematics, detailed "trajectories" of learning have been determined (Sztajn et al. 2012). Such trajectories represent ordered expected tendencies determined through empirical research designed to identify highly probable steps students follow as they develop their initial mathematical ideas into formal concepts, recognizing that each student's path can be unique. However, the limited empirical evidence for learners' trajectories in the development of understanding and skills in Computer Science, together with relatively limited understanding of pedagogy compared with other disciplines, presents challenges for specifying structure and organization of the curriculum. Curricula design may be guided by epistemological considerations and other constraints (Young 2013; Winch 2013) and later informed by empirical evidence. Typically, therefore, the current structure of curricula is defined by "best guesses" by subject experts and experienced teachers. A promising approach that is exemplified by the recently redesigned curriculum for Poland (Webb et al. 2017) uses a spiral structure where three key elements are

incorporated at each level, but their emphasis and the examples used change as the students progress through the years. In the Polish curriculum, the three key elements are:

1. Problem situations, cooperative games, and puzzles that use concrete meaningful objects – discovering concepts
2. Computational thinking about the objects and concepts – algorithms and solutions
3. Programming

The basic idea of a spiral curriculum is well-known in curriculum design and was proposed originally by Bruner (1960). A major advantage of the spiral structure is that students revisit key concepts regularly but with different examples. The idea of revisiting key concepts but with increasing complexity works well for a Computer Science curriculum where clearly the three elements identified above can be tackled at different levels of complexity. This revisiting of key ideas is useful for developing deep understanding of complex concepts and probably particularly critical for learning programming, which is known to be difficult and to require much practice (Robins et al. 2003). There is still a need for detailed empirical research to gain a better understanding of learning trajectories, but some progress has been made in relation to programming constructs (see, e.g., Rich et al. 2018).

A consensus regarding the best starting age for Computer Science being young, about 5–7 years old, emerged from a comparison of curriculum development considerations in Poland, the UK, and Australia (Webb et al. 2017). The availability of programming environments and other software designed to enable younger learners to learn programming also supports this early development of Computer Science learning (Duncan et al. 2015). Arguments for starting Computer Science at an early age include (1) learning programming is difficult, but a consensus is emerging that learning some of the techniques, approaches, and thinking involved in programming at a younger age enables more students to become successful in programming and (2) developing student

self-efficacy in programming and Computer Science at an earlier age may reduce the gender gap (Duncan et al. 2015; Webb et al. 2017).

Summary and Conclusion

In summary, concerns in recent years over the loss of Computer Science from the school curriculum have led to the redevelopment of curricula in many countries. These development processes, typically led by subject experts and experienced educators, have shown a consensus regarding key conceptual areas and important techniques in the academic discipline of Computer Science. Although there is as yet insufficient detailed evidence of students' learning trajectories to be confident of how progression should be structured into curricula, using a basic spiral curriculum structure is a promising approach that enables key concepts to be regularly revisited at increasing levels of complexity. Ongoing research is needed to develop and test learning trajectories for knowledge and skills in Computer Science across all school-aged learners.

Definition

Based on computer information systems, data mining (DM) is a technique designed to scan huge data repositories, generate information, and discover knowledge (Vlahos et al. 2004). By applying different tools, DM seeks hidden relationships in raw data in order to discover data patterns. Therefore, DM can play an important role in unveiling a broad set of findings and, consequently, offers valuable support in decision-

making. The incorporation of DM into the educational arena has given rise to a new research field called educational data mining (EDM) (Anjewierden et al. 2011). In this case, the aim is to design models, tasks, methods, and algorithms for exploring data from educational settings (Peña-Ayala 2014). Altogether, they can help to improve management activities in educational institutions, thus empowering the performance of educational managers.

Introduction

Many evidences support the statement that knowledge is among the main assets of organizations (Nonaka et al. 2008). Part of the organizational knowledge resides in the minds of employees, as intrinsic knowledge, and another part is stored as data in companies' repositories. In both cases, they consist of hidden knowledge, and, as with any other resource, the organizations cannot afford to misuse it. This way, as the knowledge management approach has proven to be an effective means of gathering the intrinsic knowledge of the organization's personnel and convert it into explicit knowledge, it is also important to explore the hidden knowledge in an organization's data and transform it into explicit knowledge. All these efforts can greatly contribute toward improving the decision-making process. DM arises as a powerful approach to aid in the accomplishment of this goal. Consequently, it is worth managers being knowledgeable about this technique.

Data Mining

The starting point of a DM approach is the availability of data repositories. The development and ubiquitous use of information technology have led to all kinds of organizations, almost inadvertently, disposing of datasets resulting from their core activities. Information about customers, personnel, transactions, etc. is stored in electronic records. In some cases, repositories are comprised of heterogeneous datasets; sometimes their size is so huge that it makes it difficult to extract useful

and comprehensive knowledge from them. Thus, the raw material – the data – can be assimilated into a “mine” with potential treasures within. The challenge is to develop and apply the appropriate tools needed “to extract” the hidden wealth as useful and comprehensible knowledge. In turn, this knowledge constitutes the basis for improved decision-making. The main difference with statistical analysis lies in the fact that DM involves methods that search for new and generalizable relationships and findings, rather than attempting to test prior hypotheses. This difference in the approach followed is the reason why data mining is also referred to as “knowledge discovery” in databases (Collins et al. 2004).

DM technique originated within this context, with the aim of discovering hidden and nontrivial relationships in information, of various types, extracted from large amounts of data (Campagni et al. 2015). Many areas have benefited from adapting the DM technique to solve their problems – among them, finance, healthcare systems, marketing, stock markets, telecommunication, manufacturing, and customer relations. In fact, it can be recognized as a contemporary tool for building knowledge management systems (Jashapara 2011). DM is a broad concept grounded on a set of disciplines, such as statistics, artificial intelligence, and computer science. Different subsets contribute to the development of DM – among them, probability, machine learning, natural language, neural networks, database management systems, etc.

The literature offers a broad set of experiences, demonstrating that statistical methods are well-established tools for analyzing data and extracting useful information. However, DM emerges as a fresh approach to understanding hidden patterns and data prediction. A reason explaining why DM has turned out to be very popular among researchers lies in the many standalone or desktop data mining tools available on the market. The following can be cited as examples: Microsoft Excel, SPSS, Weka, Protégé as Knowledge Acquisition System, and Rapid Miner. Some of them (e.g., MS Excel Mining tool) are normally available to instructors and educational managers, and they can benefit greatly from the existing knowledge of Excel.

The development of the DM technique usually follows one of two main approaches. The descriptive approach focuses on producing patterns that explain or generalize the intrinsic structure, relations, and interconnections of available data (Peng et al. 2008). The predictive approach centers on estimating unknown or future values of dependent variables based on the values of related independent variables (Hand et al. 2001). To follow either of these approaches, a number of methods and techniques can be adopted. A sample of them includes Markov models, Bayes theorem, decision trees, linear regression, frequencies, and hierarchical clustering.

Educational Data Mining

The International Educational Data Mining Society (2018) defines educational data mining (EDM) as an “emerging discipline, concerned with developing methods for exploring the unique and increasingly large-scale data that comes from educational settings and using those methods to better understand students and the settings which they learn in.” Thus, EDM is a relatively recent research area that explores and analyzes the information stored in student and institutional databases in order to understand and improve the performance both of the student learning process and of educational institutions. Data is analyzed by using statistical and algorithms with the aim of resolving problems of an educational nature and improving the entire educational

process. EDM is a growing research area that involves researchers from all over the world from both different and related areas (Campagni et al. 2015).

According to Peña-Ayala (2014), close to 98% of the published works about EDM have appeared since 2000. EDM has shifted from isolated papers published in conferences and journals to dedicated workshops, an annual international conference on educational data mining (<http://www.educationaldatamining.org>), a specialized journal on EDM (*Journal of Educational Data Mining*), as well as books and handbooks. Although focused on a specific scope, the educational setting, EDM shares with other disciplines its basic principles. Therefore, most of the processes that format and refine data, as well as the tools adopted to handle the datasets, are the same that can be found in other instances where the DM technique is applied.

Process and Tools in EDM

Slater et al. (2017) proposed a set of guidelines to facilitate the work of educational researchers and practitioners when using the DM technique. The following paragraphs summarize the suggested steps and tools that can potentially be adopted (Fig. 1).

The data used during the EDM process should respond to the objective of the research; thus, the correct adoption of the data source is of great importance, especially in environments with different databases which can misdirect the focus of

Data Mining for Educational Management,
Fig. 1 Steps in data mining

the researcher. In educational settings, data is stored in repositories that might appear in forms and formats that do not enable them to be analyzed directly. Often, educational researchers and practitioners work with data recorded in forms that are not immediately amenable to analysis, as could be the case with data retrieved from log files or learning management systems (LMS). Some characteristics of these types of educational data mean that it may be defined as messy; sometimes incomplete; fragmented in several parts that must be merged; and occasionally unfamiliar, inconvenient, or in highly unusual formats. Before performing an analysis, the data should offer a meaningful format. In addition, data needs to be cleaned and cases and values that are not simply outliers, but clearly incorrect, removed (i.e., cases where birth dates have impossible values). An example of tools well suited for the manipulation, cleaning, and formatting of data are Microsoft Excel, Google Sheets, and the EDM Workbench.

The next step after data adaptation to a workable format is the analysis and modelling of the dataset and the validation of the resulting models. There is a full range of DM algorithms. According to the objectives pursued, a certain algorithm is to be adopted. The knowledge of the data miner is crucial for choosing the correct approach. Furthermore, a high degree of knowledge of application domains is required to interpret results and evaluate whether further exploration is needed. Additionally, data expertise is required to explain strange patterns that may be due to data pollution or other causes, such as data conversions. Therefore, the analysis step may be subject to a number of uncertainties, and, consequently, the data miner is advised to follow a holistic approach. A set of tools that are appropriate for this task include RapidMiner, Waikato Environment for Knowledge Analysis (WEKA), KEEL, KoNstanz Information MinEr (KNIME), Orange, and SPSS.

A final step, once the analysis has been conducted and the results validated, is that of disseminating the output in legible and informative visualizations. Occasionally, good visualization schemes are crucial for deriving meaning

from data. Therefore, the adoption of appropriate tools and methods for visual analytics can effectively support academics and practitioners in gaining knowledge and insight from data, as well as communicating its implications. Although many of the aforementioned tools are accrued with graphical data displays, researchers and practitioners can make use of a set of tools designed to create polished and informative graphs, charts, models, networks, diagrams, and other forms of visualized information. Examples of this kind of tool are Tableau, D3.js, and InfoVis. A final consideration for researchers and practitioners of EDM, as pointed out by Slater et al. (2017), is that no *one* tool is ideally suited to conducting the entire process of analyzing datasets from start to finish. As different tools are uniquely suited to different tasks, they must be carefully chosen in order to take advantage of their potential.

Limitations of EDM

Most data mining techniques work best with very large samples. In this regard, Andonie (2010) pointed out that some data mining tools, such as neural networks, may not be able to accomplish the goal of understanding hidden patterns, since small datasets cannot provide enough data to fill the gaps. Several authors concluded that small datasets limit the scope of the DM technique (Yuan and Fine 1998). However, in the daily life of academic institutions, there are many situations where the most common is the availability of small datasets. The data which is collected on courses that students take is a good example of such a situation; even if a relatively large group of students attends the course, the relevant data is usually considered a small dataset. This constraint raises an important barrier to adoption of the DM technique in the educational arena. Therefore, a likely scenario could be a wide availability of contemporary DM tools but the impossibility of using them reliably because the available data is limited and clearly falls into the category of small data sets. However, on the contrary, some researchers clearly support DM generally not being limited to large datasets. Specific use

of DM tools for structured small datasets can also offer reliable results (Nooraei et al. 2011; Natek and Zwilling 2014). Another limiting factor concerns privacy issues; in data mining projects where personal data is used, it is important for the educational management team to be aware of the legislation, all the more because data may belong to underage students.

Classification of EDM Functionalities

Peña-Ayala (2014) analyzed a sample of 240 EDM works published between 2010 and 2013. His research extended and updated previous works. According to the characteristics and objectives pursued in each publication, a classification based on EDM functionalities was proposed. Six groups were identified, the contents being of interest to academics and practitioners because of the implications for further research and for decision-making within an educational setting. The improvement of the performance of the student learning process arises as the main *leitmotiv* of most works. From the point of view of educational managers, the information acquired, thanks to the use of EDM techniques, can contribute to the development of better politics, plans, and actions at all levels. The groups of EDM functionalities identified were the following:

1. *Analysis of student modelling.* This group includes the highest number of works in EDM. Within this group, all kinds of student traits, actions, and achievements are considered as part of this functionality. The issues addressed by works in this category include instruction and learning styles, resource usage, analysis and prediction of academic achievements, student success factors, students' mental states, domain knowledge, learning trajectories, knowledge tracing, and skills.
2. *Analysis of student behavior modelling.* This group includes research focused on the analysis, description, and evaluation of student behavior. Among the issues that are subject to study and characterization, the analysis of students' contributions, persistence in online activity, careless attitudes, user-system interaction, self-adaptation, collaborative activities, solving styles, ability, outcomes, understanding, behavior, task completion, and final marks stand out.
3. *Analysis of student performance modelling.* This functionality covers research and practical works oriented toward dealing with failure, success, students' response times, time needed to solve a problem, preparation for future learning, knowledge mastered, learning progression, response patterns, and learning achievements. The goal is to aid educational staff to supervise and assess, in a timely manner, students, with the aim of anticipating adjustments. Educational management teams could find it of interest to promote this facet of DM among teaching staff to improve student performance.
4. *Analysis of assessment.* The group of EDM applications, centered on assessment functionality, has as their main goal the evaluation and control of efficacy, efficiency, and quality of the evaluation systems, as well as the inclusion of instances aimed at assessing the degree of user satisfaction of all kinds. The issues covered in this group include, among other things, the inquiry process, learned skills, discovered relationships among responses, difficulty levels of problems, student accuracy, learning activities, misunderstandings, and the merits and pitfalls of standardized tests.
5. *Analysis of student support and feedback.* This functionality aims to develop enhanced computer educational systems by means of their personalization and customization to meet students' demands. Some of the instances considered under this aggrupation include dialogue analysis, generation of hints, decision-making, customized feedback, reinforcement, recommendations, opinion about teaching behaviors, advice content, student annotations, dealing with emotions, and stimulation of competences.
6. *Analysis of curriculum, domain knowledge, sequencing, and teacher support.* This functionality represents heterogeneous tasks and components. This group includes

those instances that do not fit into previous classification, although they cover important facets of the educational process. Among the topics addressed include content authoring, knowledge description, teachers' collaboration in tailoring curricula, personalized searching of educational content, user-tool interaction, curriculum analysis, scheduling of learning activities, design of hierarchical content structures, and teacher mentoring behaviors. Peña-Ayala (2014) expects that the evolution of this sort of functionality will see an increasing demand in academic interest.

Implications for Educational Management

An educational institution maintains and stores various types of student data; it can range from student academic data to their personal records, including parents' incomes, qualifications, etc. This repository can potentially allow managers and teachers to extract useful information in order to make management-level decisions. Although the scope and implications of managerial decisions is not the same, depending on the decision-maker (e.g., educational manager or teacher), both actors can greatly influence the quality of the teaching-learning process. Decisions at the educational management level can lead to actions such as the construction of new facilities to respond to social and educational demands, hiring new staff with specific expertise or skills, developing programs for the deeper involvement of parents, etc. On the other hand, decisions at the teacher/instructor level are more limited in scope but can equally contribute to the improvement in quality of the teaching-learning process in the classroom (e.g., rapid response to abandonment attitudes, student success predictions, etc.). Therefore, EDM should not be conceived of as a technique aimed at a specific actor within the educational arena; it is of interest to all those who can, at their own level of influence, contribute to a better performance of the educational process.

The functionalities of EDM described in the previous section obey actions that can be promoted either at the teacher/instructor level or at the managerial level. The management of schools and colleges and, of course, the management of government bodies have a wider capacity to influence and convince researchers and practitioners to learn about and adopt the EDM technique. The literature shows that the adoption of EDM has contributed to improving the educational process by, for example, (i) predicting students' performances using a dataset consisting of students' gender, parental education, their financial background, etc.; (ii) predicting student learning outcomes based on attributes such as attendance and performance in class tests and assignments; (iii) student modelling using the educational history of students; and (iv) predicting the academic dismissal of students and the GPA of graduated students in e-learning, using regression analysis and classification (Dutt et al. 2017). These evidences show that EDM can, in a broad sense, arise as an important tool for improving the work of educational managers.

Summary

EDM has emerged as a paradigm oriented toward designing models, tasks, methods, and algorithms for exploring data from educational settings. The potential opportunities provided by EDM, which claims new paradigms for enhancing the scope, quality, efficiency, and achievements of educational systems, are promising in the field of education due to it being a high priority for global society. In recent years, a wide array of tools has emerged for the purpose of conducting educational data mining (EDM). These tools have proven their utility with respect to common data pre-processing and analysis steps in a typical EDM project. Educational management should consider EDM as an opportunity for improving the quality of decision-making, both at their level and at the teacher/instructor level, thanks to its potential for discovery of hidden patterns of information; thus, their involvement is crucial

in order to take advantage of this paradigm. However, this technique shows some limitations that must be taken in consideration so as not to encounter the potential pitfalls that, in the long-term, may end up causing mistrust and doubt regarding the usefulness of EDM.

Data science is the art and science of turning data into insights. Data science is a cross-disciplinary area that applies various concepts, methods, algorithms, and processes from diverse scientific

disciplines, like mathematics, statistics, computer science, and information science. Data science aims to apply these methods and concepts employing suitable integrated development environments and tools to generate knowledge from partially unstructured, incomplete, and distributed data collections. Depending on the application context, this knowledge can then be transformed into concrete action, e.g., when companies make strategic decisions on future business policy based on trend analysis (Song and Zhu 2017; Parks 2017).

In order to correctly assess the significance of data science education (DSE) in education and training at schools and universities, it is necessary to firstly deal with technical concepts of Data Science (DS) and Big Data and their areas of application as well as their social and economic impacts in society.

Subsequently, considerations can be made as to how technical contents and methods of data science can be integrated into existing curricula of schools (e.g., mathematics, computer science, STEM, social, and cultural science subjects) and universities (computer science, science, social sciences, humanities, ...) or whether DSE/DS should be an independent subject in schools or universities.

A look at the current literature shows that there are slightly different definitions for DS and Big Data. Also, the field of applications of methods and concepts of DS is vast and diverse and covers many social and scientific areas.

Data Science

Therefore, the following aspects of DS will be considered:

- The data sets used (Big Data, partly unstructured data from different sources, handling of probability values of data, handling of uncertainty and missing data, ...)
- The computational and mathematical methods used in Data Science (e.g., machine learning, deep learning, artificial intelligence, algorithms, neural networks, self-optimizing genetic algorithms, probability theory, stochastics)
- The technological methods of data collection, processing, storage, distribution (e.g., data from business processes, data from production processes, data streams from sensors, social networks (user-generated data), (self)-tracking, open statistical sources, health care, ...)
- The application areas of Data Science in society and the social, ecological, economic, political, and ethical issues
- Data mining process models (e.g., CRISP-DM)

In the following, some mathematical, statistical, computational, technical, and human-social aspects of Data Science will be discussed in more detail, see, e.g., Blei and Smyth (2017).

Big Data

In a society characterized by increasing digitalization, a wide variety of communication, interaction, and production processes are leading to the creation of extensive, distributed, and independent data collections. In contrast to structured data collections, as we know them from traditional computer science databases, these data are entirely different or not at all structured and sometimes even incomplete. These databases are often referred to by the generic term “Big Data.” In the literature, there are different definitions, which nevertheless refer to essential common characteristics of Big Data (DejaVVu 2012; Chen et al. 2014; De Mauro et al. 2015; Alharthi et al. 2017; Zhang et al. 2017).

Such a consensual definition of big data usually contains the following properties of Big Data, described as the “5 Vs” (see Zhang et al. 2017):

Variety represents the different data types gathered from various sources. The data types are mostly multiplex and consist of, e.g., text, symbols, images, videos, audios, and sequential data streams from sensors.

Velocity characterizes the speed at which the data is generated, transferred, and has to be processed. Some applications can access stored data in batch mode and are not time-critical, while others require continuous real-time processing of the data, sometimes at high speed.

Volume represents the huge amount of data produced from different sources.

Value addresses the (hidden) information contained in the data. From this extracted information, knowledge can be generated that can be of great use and value to individuals or organizations. Value is about understanding the meaning of the data for a specific application context. This understanding of meaning can lead to economic gain but also to political or social advantages for those who have access to this knowledge. This aspect concerns the relationship between data, information, and knowledge, as well as the question of user interests and accessibility to these large databases.

Veracity concerns the increase of the quality of data and the extracted information. Since the data originate from different sources, they must be appropriately combined and analyzed, and the results must be verified concerning their trustworthiness. Data may be incomplete, and the reliability of the data is not assured. The processing of big data, therefore, requires the handling of uncertainty, probability values, and missing data. Only in this way, a new quality of the aggregated data can be achieved and thus a qualitatively higher benefit for the users.

The access and analysis of Big Data place high demands on the evaluation methodology and the IT-infrastructure.

Data Sources

In a society characterized by digitalization and globalization, data is generated by a variety of processes in very different areas.

In companies, communication and cooperation processes can result in large amounts of data. On the one hand, they concern internal communication and production processes. On the other hand, they also concern communication with other companies (B2B) or with customers (B2C). Some of this data is only available within the organization, and others can be used by other users. The data form an essential information basis for the organization of the enterprise and the planning of its future business activities.

In addition to documents of various types, employees also generate digital artifacts resulting from their communication in various digital media, such as email, chat, articles in wikis and group communication tools, group calendars, etc. In this way, cross-company artifact actor networks (AAN, Riss et al. (2011)) are created, which can also represent a valuable data sources.

Another essential data source is scientific institutions with their research results published in various media.

Furthermore, numerous governmental and private organizations (e.g., NGOs) publish data from their respective fields of activity (e.g., statistics on government action, social statistics, regional and global economic data, ecological data on the state of the environment, statistical data from the health sector, etc.).

A further group of data sources is process-data provided by different technical-physical sensors. These include, for example, measurements from the environment, such as weather data, climate data, data on water quality, air pollution, etc.

The Internet of Things (IoT) and the close collection of data in residential areas (Smart City) and households (Smart Home) generate further massive databases. The 5G-technology enables very fine-grained motion profiles of people (tracking of mobile devices, self-tracking) and vehicles (toll, autonomous driving), which are also based on the generation of large data pools.

The use of the Internet with its wide range of services is also a source of vast data collections. In addition to video and audio streams from various Internet platforms and websites, it is above all the data traces voluntarily (user input) or involuntarily left behind by users (tracking) that generate immense amounts of data. In particular, the posts and likes left behind in the social media (e.g., Twitter, Facebook, etc.) as well as the usage data, often hidden collected by apps on mobile devices (evidence of mobile apps), offer various interested parties a variety of evaluation options.

Many of these sources are publicly accessible or are available for assessment for a fee.

For DSE purposes, some data sources, mentioned above, are also available and can easily be exploited in a wide variety of subject areas,

especially from Open Data Sources (Gandomi and Haider 2015; Katal et al. 2013; Deokar et al. 2018; Ruijter et al. 2018).

Methods of Data Science

In order to use these distributed, unconnected semi- or unstructured data collections and to extract hidden patterns and information, a combination of mathematical, statistical, and informatics methods is required. In order to select the correct evaluation strategies concerning the evaluation interest, to pose the basic appropriate evaluation questions and to interpret the meaning of the gained information correctly concerning the evaluation context, domain-specific context-related knowledge is also required.

It follows from this that there is no generic uniform methodology of DS, but in each case, a combination of methods appropriate to the question and the complexity of the data collection is necessary.

Besides a phase model, which determines the sequence of individual evaluation steps (see below), above all methods of the field of artificial intelligence (AI), like machine learning (ML) and deep learning (DL), are to be called here. AI functions as a generic term for the application of different mathematical and informatic methods to which logical methods and knowledge-based systems also belong.

Machine learning (ML) mainly applies different mathematical methods in order to structure data collections in a hierarchical order, e.g., as a decision tree. Also, the clustering of data or rather data vectors, according to similarities, is an often-used method.

Their goal is to recognize patterns in the data. Furthermore, statistical methods are also used if a complete analysis of the data sets is not possible due to missing or insufficient data or too many dimensions to be considered. In this way, it is possible to essentially reduce the number of data dimensions to be considered in machine learning.

According to the laws of probability theory, only the most “probably” useful dimensions are considered concerning the domain of knowledge,

which considerably reduces the calculation effort (feature engineering) (Reid Turner et al. 1999).

In machine learning and feature engineering, the problem of unequal treatment of learning algorithms must also be considered (process fairness in ML), so that self-reinforcing effects do not prevent satisfactory results (unbalanced predictions, automated decision-making). To solve these issues, performance metrics for ML models are generated and applied. Furthermore, it is possible to influence the weighting of certain variables in the calculation models by targeted human intervention based on domain-specific knowledge.

In deep learning, a specific discipline of machine learning, neural networks are also used to find relevant patterns in the data collections or for pattern recognition in addition to the methods mentioned above.

In the broadest sense, neural networks are based on biological concepts of information processing in the brains of living beings. Data and information are realized by the connection of neurons, which can be represented as graphs with nodes and edges. By developing new or deleting other connections, adjusting the weights of the connections between the neurons and changing threshold values above which connections are considered relevant, calculations can be carried out on the computer in many iterative steps, which may then lead to the discovery or recognition of patterns (Al-Masri 2019).

Backpropagation networks consist of an input layer of neurons of an output layer and one or more intermediate layers.

Neural networks are fed (trained) with data utilizing an activation and input function, while propagation and output functions are responsible for the calculation of state changes in the network or the output of the calculated values and information.

By training a neural network, the weights between the neurons can be adjusted for pattern recognition, so that specific input patterns (e.g., photos of a person) always lead to a particular output pattern (e.g., recognition of the person).

Convolutional neural networks (CNN) are specific neural networks that are mainly used for the classification of image data. In order to reduce the

computational effort for the pixel data of images, these networks are preceded by computation methods that reduce the effort before the neural network is applied (A Beginner's Guide to Neural Networks and Deep Learning 2019).

Algorithm models for classification or regression are most frequently used in combination with neural networks for supervised machine learning. However, models for unsupervised learning are also used, which include methods of clustering and dimension reduction. In supervised machine learning, functions are calculated on the basis of training data whose output is known (pattern recognition). In unsupervised machine learning, previously unknown structures in the data are to be extracted without the specification of a target variable.

Overall, the described methods of ML and DL are mainly based on the combined application of mathematical and informatics methods. From the field of mathematics, there are subareas such as proposition and predicate logic, relational algebra and graph theory, as well as search and optimization methods, which in turn are based on concepts of linear algebra and analysis. Other important mathematical disciplines required for the methods of Data Science are probability theory and stochastics. From a computer science perspective, the methods of Data Science mainly include the fundamentals of modeling and programming, algorithms and data structures, databases, software development, and software architectures.

In Data Science methods, it is difficult to distinguish between mathematical and informatics parts of the methodology, because there is a high degree of overlap between the two parts. From a computer science perspective, it is particularly important that the data is machine-readable and can be processed with suitable software tools and a powerful hardware architecture. In order to be able to develop appropriate problem-related questions and to adequately evaluate the results achieved against the background of the application context, a third field of knowledge beyond mathematics and computer science is required: domain-specific expertise. Thus, it becomes clear that DS is not only a field that requires multiple

methods but also a multi-perspective view of the problems by experts from different fields. These different requirement areas for DS will later also be considered in the design of DSE curricula at school and university in an appropriate form and in relation to target groups (see below) (LeCun et al. 2015; Blum et al. 2018; Al-Masri 2019; Nielsen 2019; Maimon and Rokach 2010; Schmidhuber 2015; Chattamvelli 2016; Artificial Intelligence 2019).

Data Mining Process Models

The use of mathematical and informatic methods, as well as the application of domain-specific knowledge during the preparation and analysis of data, must be sensibly integrated into an overall concept of data mining appropriate to the problem and in order to achieve useful evaluation results.

This process-related aspect of data-handling can, on the one hand, be viewed from the perspective of the data (data life cycle) and the associated activities of data preparation. On the other hand, it can be regarded from the perspective of business and working processes and the associated evaluation interests (data mining process models). Both partly empirically founded concepts show a particular agreement with some differences in the detail.

The activities of data manipulation assigned to these phase models can be linked to phases of learning in DSE projects and the competency requirements to be acquired there. These phase-related activities can then also serve as elements of a theoretically founded competence model or to justify DSE curricula (see below) (Faundeen 2012; U.S. Geological Survey et al. 2017; Data Life Cycle 2019; Sivarajah et al. 2017; Wirth and Hipp 2000).

The models partly are of different granularity, partly consider technical aspects of the implementation of concepts of data processing and therefore contain a different number of elements.

The data life cycle model, which is based on a project funded by the US National Science Foundation, comprises eight phases (see Data Life Cycle 2019):

- **Plan:** Description of the data that will be compiled and how the data will be managed and made accessible throughout its lifetime.
- **Collect:** Acquisition of the data (e.g., by hand or with sensors or other instruments; the data are transferred in a machine-readable form).
- **Assure:** The quality of the data is assured through checks and inspections that includes cleansing of the data.
- **Describe:** Data are accurately and thoroughly described using the appropriate metadata standards.
- **Preserve:** Data are submitted to an appropriate long-term archive (i.e., data center).
- **Discover:** Potentially useful data are located and obtained, along with the relevant information about the data (metadata).
- **Integrate:** Data from disparate sources are combined to form one homogeneous set of data that can be readily analyzed.
- **Analyze:** Data are analyzed in order to extract relevant information.

Other concepts additionally amended further phases including some technical aspects of data handling (see, e.g., Grillenberger and Romeike 2017, pp. 35).

- **Model:** Structuring the data in a way that it can be stored and accessed efficiently.
- **Implement:** Implement the data model and store the digital data.
- **Visualize:** Visually presenting and editing information to make them better understandable.
- **Evaluate:** For example, the analysis results and the quality of data they are based on.
- **Share:** The data (original or aggregated data) and/or results of the analysis.

Other, somewhat more complex models also emphasize the importance of integrating external expertise into the evaluation and application process as a cross-phase necessity: “Community Watch & Participation” see (DCC Curation Lifecycle Model 2019).

The preparation and evaluation of the data in the data life cycle can be structured according to

another model concerning three groups of challenges (Sivarajah et al. 2017, p. 265).

- **Data challenges:** The group of the challenges related to the characteristics of the data itself (see above: volume, velocity, variety, variability, veracity, visualization, and value)
- **Process challenges:** Encountered while processing the data (data acquisition and warehousing, data mining and cleaning, data aggregation and integration, analysis and modeling, and data interpretation)
- **Management challenges:** Tackle, e.g., the privacy, security, governance, and lack of skills related to understanding and analyzing data

Concerning the evaluation and application interest of companies and organizations with the perspective of determining concrete action strategies, the use of analytical methods in the context of Big Data can be divided into the following phases: (Sivarajah et al. 2017, p. 266).

- **Information:**
Descriptive analytics that help in understanding, e.g., “What happened in the business?”
Inquisitive analytics that help in comprehending, e.g., “Why is something happening in the business?”
- **Insights:**
Predictive analytics that help in anticipating, e.g., “What is likely to happen in the future?”
- **Decision:**
Prescriptive analytics that help in responding “So what?” and “Now what?”
- **Action:**
Preemptive analytics that help in recommending “What is required to do more?”

There are various data mining process models with different phases, especially for the preparation and analysis of Big Data and its use for strategic entrepreneurial action.

The iterative and interactive KDD model (Knowledge Discovery Databases) has nine steps. The SEMMA (Sample, Explore, Modify, Model, Assess) model was developed by SAS institute and has five different phases.

The best-known Data Mining Process Model, which has been repeatedly refined over the years, is CRISP-DM (Cross-Industry Standard Process for Data Mining).

It originally was launched in late 1996 by Daimler Chrysler (then Daimler-Benz), SPSS (then ISL), and NCR and has six steps or phases: business understanding, data understanding, data preparation, modeling, evaluation, and deployment (Shafique and Qaiser 2014).

These phases can be applied in different order, and repeatedly, as data mining is seen as a cyclic process. Each phase describes specific tasks and aspects of the process, and thus can also be used to describe affordances for a data science curriculum. Therefore, in the following, each phase will briefly be discussed (see Wirth and Hipp 2000).

Business Understanding

This is an initial phase focusing on understanding the objectives and requirements from a business perspective, in other words: understanding the problem domain. This phase aims at uncovering important factors like success criteria, business and data mining objectives and requirements, as well as business terminologies and technical terms. Developing a preliminary project plan, designed to achieve the objectives, is also part of this phase.

Data Understanding

This phase typically starts with data collection and checking the quality of the data. Exploring the data for hidden information and deriving hypotheses are also important tasks of this phase.

Data Preparation

This phase focuses on the selection and preparation of final data sets. Tasks of this phase include table, record, and attribute selection, data cleaning, construction of new attributes, and transformation of data for modeling tools (construct data; derive attributes; integrate, merge, format or reformat data). During this phase also a rationale for inclusion/exclusion of data should be generated (data set description/data cleaning report).

Modeling

In this phase, various modeling techniques are selected and applied in order to build a model, according to modeling assumptions. Also, the development of a test design and the application of tests in order to assess and possibly revise the model and its parameter settings has to be conducted during this phase. Since some techniques require specific data formats and there is a close link between data preparation and modeling, it is sometimes necessary to construct new data.

Evaluation

This phase focuses on the evaluation of the obtained models, and it is to decide about the quality of the results with regard to the data, the applied algorithms and if the model will be able to achieve the business objectives. At the end of this phase, next steps and a list of possible actions should be determined based on the model and the data analysis.

Deployment

In this final phase, the gained knowledge has to be delivered and presented to the customers.

This can be done by a simple final report or in a more complex way that includes a presentation of the results and the delivery of documents (e.g., project review, monitoring and maintenance, and further action plan) that allow the implementation of a repeatable data mining process.

Application Areas and Social Impact

The consideration of process models for the analysis of big data and the extraction of relevant information has so far mainly been related to the area of companies and organizations. However, the presented process models can also provide important clues for the methodical and content-related design of DSE projects and the competences to be acquired by learners. However, DSE must not only refer to the mathematical, informatics, and technical aspects of data science but should in any case also consider the social effects of the application of DS concepts in society. This applies both to the training of DS professionals in higher education and to DSE at the secondary level. Both DS-professionals and

students should be aware of the social impact of DS in society in responsible informatics-system design (professionals) as well as in a competent political and social participation in society (students). A basic understanding of the social effects of the application of DS methods requires at least a basic knowledge of these methods.

Social impacts of DS affect many areas of society that cannot be described in detail here. It is essential for the content selection of the topics in DSE at the secondary level that they relate to the reality of the students' lives. In order to gain an overview of the diversity of possible topics, the social impact of applications of DS methods can be structured according to different aspects:

- Structuring according to the complexity of the social context
- Structuring according to social areas of application
- Structuring according to social impact type

In order to analyze a DS application scenario and assess its social impact, the dimensions can also be combined and thus open up a multi-perspective view of a selected subject area. These structural dimensions are not disjunctive and partly condition each other in a complementary way (see below).

Structuring According to the Complexity of the Social Context of Application Scenarios

Depending on the complexity of the social context of the application scenario, the use of DS-concepts has an impact on the individual level, on the level of groups, an organization or a company, on the whole society, or even on an international or global level. These effects are often only to be understood in the interdependent interaction of the different levels and complement each other.

For example, the use of voice-controlled, networked assistants in a Smart Home can provide useful services to the residents of an apartment. On the other hand, residents can transmit a large amount of private data to the service provider either intentionally or unintentionally. These processes could violate the privacy of the residents. In a complementary way, an internationally or globally

active company that collects such data in a large number of households can build up a massive data collection. This data can then be used to provide private households, for example, with user-specific information (recommender systems, targeted advertising). On the other hand, the company can use this data for the further development of its own corporate strategy or sell the customer data profitably to other interested parties.

Structuring According to Social Areas of Application

There is a multitude of social application areas in which DS methods and concepts are used. Here, too, the application areas cannot be considered entirely independently of each other, and their effects overlap or influence each other. These societal domains can be regarded as necessary:

- *Economy*: For example, economic data of companies, states, associations of states in order to obtain action strategies for controlling the economy at a particular level (corporate strategy, state, and supranational economic policy).
- *Energy*: For example, data to control complex energy system depending on generation and consumption of energy.
- *Environment/ecology*: For example, environmental and weather data that can be used for weather and climate forecasts.
- *Disaster response*: For example, data from catastrophic events (storms, earthquakes, floods, and volcanism) to develop strategies to avoid or reduce risks.
- *Healthcare*: For example, behavioral and health data of individuals as a basis for research into the causes of diseases, a system for diagnosing diseases based on pattern recognition.
- *Politics*: For example, statistical data from various sources as a basis for strategic political decisions.
- *E-government*: For example, ADM-algorithms (automated decision-making) for automated processing of administrative procedures. Based on training data, group membership correlates with the target variable. ADM concepts can be used to make decisions for cases and groups to be treated in the same way.

- *Education*: For example, data from learners in e-learning systems (learning analytics).
- *Traffic*: For example, intelligent traffic systems, autonomous driving based on 5G data.
- *Smart Home, Smart Cities*: For example, user data of services offered in households and communities to control the use of service offers.
- *Culture*: For example, the use of video data from many films to generate any artificial scenes with the persons concerned, which cannot be distinguished from real scenes.
- *Life style*: For example, data generated in social media, which can be used for very different purposes (e.g., control of media usage by consumers).

Micro-targeting should be mentioned here as another example of the mutual relationship between social complexity and societal DS-application areas. Through the systematic analysis of data from social media, as well as on voter behavior and opinion research, specific target-group-related advertising measures to influence political opinion can be developed. This strategy can be realized, e.g., by posts in social media, which are only visible for a specific target group and whose opinion is reinforced in the groups' typical "filter bubble." In this way, e.g., elections can be decided at the national level.

Structuring According to Social Impact Type

The types of social impacts of DS-applications can be classified as follows:

- *Economic*: Employment, changing economic strategies
Based on the analysis of economic data or data from social media (trend analysis), entrepreneurial or governmental decisions can be made that can lead to redundancies for members of the target groups affected, but also to demand labor.
- *Political*: Political abuse and surveillance versus improved decision-making and participation

Through a mass collection of personal data, including movement data of persons (tracking, surveillance, self-tracking) in combination with pattern recognition of video recordings

provided by cameras installed in public areas, copious social control and surveillance of people can take place.

- *Social and ethical*: Participation, equality, trust, discrimination (exclusion, inclusion)
The analysis of data obtained in the above manner using DS methods can lead to the exclusion or inclusion of groups of persons, e.g., concerning state or entrepreneurial action. (Social monitoring and reward or restriction systems; access or exclusion of groups of persons concerning insurance benefits, loans or health care measures).
- *Legal*: Privacy issues, intellectual property rights (IPR), liability, and accountability.

The personal data collected on a broad basis can lead to their misuse and the violation of personal rights. This also applies to the handling of IPR, which address an essential aspect of data management. If such rights are not observed, the relationships between powerful economic or state actors and individuals can be damaged. This then affects questions of liability and accountability.

Concerning the data generated (provided, observed, derived, and inferred) (OECD 2014) and decisions made by ADM or algorithms based on DS methods, a distinction can be made between different ethical issues, which imply different social consequences:

- Inconclusive evidence (probable yet inevitably uncertain knowledge) leading to unjustified actions.
- Inscrutable evidence (lack of knowledge regarding the data being used, e.g., relating to their scope, provenance, and quality) leading to opacity.
- Misguided evidence (conclusions can only be as reliable as the data they are based on) leading to bias.
- Unfair outcomes are leading to discrimination. Actions driven by algorithms can be biased concerning numerous ethical criteria; also, the iterative calculation steps of algorithms may not guarantee fairness to the different branches and outcomes.

- Transformative effects are leading to challenges for autonomy. Algorithms, e.g., like profiling, re-ontologize, and conceptualize the knowledge domain the related real-world problem sometimes in new, unexpected ways. The results could trigger actions based on the insights it generates, though the calculation processes have not been transparent.
- Transformative effects are leading to challenges for informational privacy. The lack of transparency of some results generated by DS-methods implies that harm caused by algorithmic activity is hard to debug but also that it is rarely straightforward to identify who should be held responsible for the harm caused (e.g., exclusion from a governmental service; car accident during autonomous driving) (Mittelstadt et al. 2016; Gupta et al. 2018; Mantelero 2018; Lepri et al. 2016; Cuquet et al. 2017; Bigdatasoc 2019; Trajtenberg 2018).

Informatics Systems for Processing Big Data

The application of DS-methods always requires Computer Science knowledge about the software and the hardware of the analysis environment and the embedded analysis tools. Depending on the size of the company or organization, there is a wide range of complexity of the systems and the skills required to use them.

In large companies/organizations, knowledge of system enterprise architecture with its hierarchical, aggregated layers (e.g., Multilayer Model: Technology or Infrastructure Architecture, Software, Integration, Process, and Business Architecture) and the data flows caused by it is essential for the analysis and evaluation of the data (see Winter and Fischer 2006; Kearny et al. 2016; Niu et al. 2013).

Specific working environments or tools are used to collect the data, to store the original and processed data, process and visualize the data, and manage data storage and distribution sustainably. These different phases of tool's usage of the informatics working environment are closely related to the phases of the data life cycle or the phases of

the DM-process models and are used there repeatedly as required.

Standard software tools and architectures can be assigned to specific phases of the DS-DM process.

Collect Data

In this phase, access to internal data streams and data collections as well as to external data sources is required. These activities require knowledge of relational and non-relational database systems (e.g., NoSQL, MongoDB) and database languages (e.g., SQL). For access to external data sources (e.g., social media) and the subsequent restructuring of the data for evaluation purposes, access to available interfaces must be mastered (Bello-Organ et al. 2016; Ahmad et al. 2017).

Depending on the system architecture and the available tools, this requires additionally knowledge of XML, PHP, Java, C#, JavaScript, JSON, Python, etc.

Edit Data with DS Methods

In order to process extensive, sometimes unstructured data collections from different sources applying DS methods, several computing environments, available on the market, can be used. For data preparation, parallel data processing methods and more massive computer clusters are used in large companies and organizations. Free software libraries to accomplish these tasks include MapReduce, Hadoop, Mahout, etc. (Bello-Organ et al. 2016).

MapReduce is designed for implementing algorithms that allow distributing parallel processing. It divides problems into two parts by using two basic functions, mappers and reducers. The map function processes source data into sufficient statistics. The reduce function merges all sufficient statistics into a final result. Thus, any number of concurrent map functions can be processed at the same time without intercommunication.

Hadoop is a scalable framework designed for the distributed processing of large data sets across clusters of computers. It enables preprocessing procedures like filtering, sorting, and generate denser data that might contain more information and make the data suitable for additional analysis with other tools.

The scalable Mahout machine learning library enables the implementation of numerous ML-algorithms for dimensionality reduction, classification, clustering, etc. Additionally, it contains topic models and a set of recommender systems for user-based and item-based strategies.

Furthermore, several program packages and integrated development environments are available, which can be used to further evaluate the data after preprocessing or immediately apply DS methods.

These packages include, for example, the open source programming language R for statistical calculations, the language “R Markdown” for the creation of problem-oriented result reports, and the associated integrated development environment R-Studio. The latter can be used to coordinate more complex calculations with the data and visualize the processes and results and output them in different document formats. The packages also have numerous interfaces to other tools for further analysis of the data (e.g., Jupyter Notebook, see below.) (Bello-Orgaz et al. 2016).

In the simplest case, however, generic tools such as spreadsheets can also be used for the calculation and visualization of data.

If, for example, neural networks are to be integrated into the machine learning process for pattern recognition or similar evaluation tasks, appropriate development, and training tools are also available. These include, e.g., Tensor Flow, PyTorch, Keras, OpenNN, Neuroph, Neuronal Designer, and others (see The Best Machine Learning Tools 2019; Richard 2019).

Here are just a few examples of the essential functions of TensorFlow. TensorFlow is an open source software library for large-scale machine learning and deep neural network research. It applies data flow graphs consisting of nodes and edges for numerical computations. Nodes in the graph represent mathematical operations, and edges symbolize multidimensional data arrays or tensors, on which these operations are performed. TensorFlow enables the visualization of data flow between operations and thus can contribute to a better understanding of the calculation processes. Among other things, this property makes the computing environment

particularly suitable for learning with neural networks in DSE (see below).

Sustainable Storage, Backup, and Distribution of Data and Results

For the sustainable saving and archiving of raw data, prepared data and evaluation results as well as their distribution, a hardware and software architecture are required, especially in large companies and organizations. This includes storing of data in repositories with version control like, e.g., Github, Hadoop, OpenStack, Swift, and many others. In particular, access rights management, privacy and security issues, as well as the compliance with IPR specifications, have to be considered. This results in further competence requirements of data science (Rimal et al. 2011; Chen and Zhao 2012).

Data Science Education

In this section, we discuss data science curricula to give an impression of the nature of the data science education mainly at school but also in academia. To give the reader an overview, we focus on the rationale (Annette Thijs and Jan van den Akker 2009), that is the underlying philosophy of the curriculum.

In accordance with the evolution of data science out of statistics (Hardin et al. 2015), data science curricula often emerged as part of statistics curricula. Hardin et al. give an overview on data science curricula in a statistical context, thereby focusing on the specific nature of the new curriculum aspect, which is (a) the inclusion of programming competencies beyond simple scripting and (b) the inclusion of data technology and data formats in contrast to statistics education, where questions of data management and data wrangling are often omitted in order to focus on the statistical aspects. Nevertheless, statistics should be included, and therefore data science curricula typically center around a data process and “real” authentic data examples.

In general, typical current curricula are aligned to the data life cycle and process models, e.g., the CRISP-DM (De Veaux et al. 2017). That is, the curriculum organization is in some way related to

the phases and tasks of such models. This includes the notion that data science curricula include data science projects to allow learners to experience the full data life cycle. In this context, it is often suggested to also include “real data” and “real” project, e.g., projects with some real-world application (Song and Zhu 2016). Examples are data science for social good. In addition, data science curricula are aiming at integrating computational as well as mathematical (statistical) skills (topics).

In an overview study, Ridsdale et al. (2015) summarize typical curricula around the data science process with the aspects of: data collection, data management, data evaluation, and data application. For each of these phases of a data science life cycle (they call them key abilities) related competencies and tasks/knowledge are described. For example, “data collection” as key ability is refined to competencies of “data discovery and collection” and “evaluating and ensuring quality of data and sources.” The first of the competencies (Data discovery) is detailed to the tasks of performing data exploration and identifying useful data. On the finest level, a data science curriculum thus defines operations with or on data, see, e.g., Erickson et al. (2018).

DSE Project Models (Related to Data Science Process Models/CRISP-DM)

Project phases as defined for industrial use are not suitable to be implemented without adaptation in education. For example, depending on context and level, DSE curricula focus, e.g., more on computational aspects (e.g., safely and efficiently storing and retrieving of data) or statistical (e.g., proper choice of visualizations and tests) within project phases.

Another difference is a stronger focus on ethical issues in education. Such ethical and societal aspects of the curriculum are typically not included in data life cycles. For example, Ridsdale et al. add competencies like “Critical Thinking,” “Data Ethics,” or “Evaluating Decisions Based on Data” to the list of competencies and thereby enrich or change the phase “Data Application” which in the CRISP-DM is just seen as “Deployment.” Similarly, Song and Zhu (2016) change the CRISP-DM and split modeling into the phases model planning

and model building, and add the phase “Review and Monitoring” to account for the educational context.

In the following, we will briefly discuss differences in these project phases due to the educational context, briefly referring to the CRISP-DM (see above).

DSE-Project Phases Related to Business Understanding

In this initial phase, an outline or plan for the project will be developed including, e.g., understanding the problem domain and setting the goals. In education, this phase might differ. For example, from the history of statistics education and also in models of data literacy, this step is usually conceived as asking a question or posing a problem to be answered by data; but the question or the context within to find a question to be answered is chosen for suitability for the educational goals. While it is obvious that domain-specific expert knowledge is necessary for its successful design, it may be that domains are chosen that are well-known to the learners, so that they can focus on learning the data science aspects.

DSE-Project Phases Related to Data Understanding and Data Preparation

The next two phases are probably more connected in educational projects.

Again, from the history of statistics education, the task in the phases of data understanding and preparation is typically seen as specifically collecting data to answer a given question, e.g., by designing a questionnaire and conducting a survey. From a CS perspective, another typical approach would be to look at data already being collected – either with the intention to explore and understand the data, or to answer some specific questions. Typical data sources for this type of data science projects include data from sensors or from human interactions with digital artifacts. In both cases and/or in initial stages of the curriculum, the task to prepare the data is often omitted, and cleaned data is given to the learners, so that they can focus on data understanding. In order to achieve an authentic learning experience, it is

often suggested to use real data and real data projects, so that it “smells like data science.” In industrial projects, 70% or even 80% of the time can be spent with data management, including data understanding and data management: e.g., data wrangling, data transformation, coping with missing values are a prerequisite then for first visualizations and descriptive statistics. For educational projects, it does not seem suitable to use such an amount of time for data preparation. So pre-cleaned data, smaller data sets can be used to reduce the length of this phase. Typically, first projects are done with ready prepared data sets. In textbooks and libraries for data science, often such cleaned data sets are already included. So, in education, this step is rather tightly coupled with data preparation, that is, e.g., selecting data to be used for the next phase.

Data understanding is a very crucial part and includes basic descriptive statistics and data visualization, e.g., visual analytics.

DSE-Project Phases Related to Modeling and Deployment

In this phase, new insights from the prepared and selected data are to be derived. This is often connected to building a model of the problem domain, based on the data. This can be, e.g., an artificial neural network trained by the data, the result of a regression analysis, etc.

In case of a neural network, the model consists of both the overall architecture, and the specific weights of neurons based on the training phase. This model then exists independently from the data and can be used to analyze new data. It is an important insight for learners to understand that data-driven products are making decisions on cases (based on data) but doing so is grounded in past data and past cases. In addition, such a data-driven product – e.g., a recommender system – can also be adapted while in use and the model updated based on new data.

Within this perspective, the goal is then to build a product, based on the model, that can later be used. If a data-driven product is built, based on the model, then its use is referred to or prepared by the deployment phase. In data education, typical examples are projects that aim to be

effective in the students’ everyday contexts. Here projects like “data science for social good” are examples (Coulton et al. 2015; Bryant et al. 2018) or <https://dssg.uchicago.edu/projects/>.

Examples of project themes used in data science education are listed below:

- The evaluation of microblogs (tweets) regarding specific topics (hashtags) and the time course of their occurrence. For this purpose, interfaces can be used to access the raw data (e.g., <https://developer.twitter.com/en/docs>) or apply already existing analysis tools (e.g., <https://www.talkwalker.com/de/blog/7-kostenlose-twitter-analyse-tools-empfohlen-von-experten>).
- Content- and time-related analysis of communication (via different media) in accessible parts of social networks (AAN: Artifact Actor Network Analysis; e.g., Riss et al. 2011).
- Forecast of sports results, development of stocks based on past performance.
- Conducting election forecasts based on previous data and surveys conducted by the students (e.g., <http://www.bpb.de/lernen/grafstat/grafstat-bundestagswahl-2013/144674/bundestagswahl-wahl-analyse-und-wahlprognose>).
- Evaluation of data collected by students with mobile devices concerning specific questions (e.g., scientific field excursions such as in Schaal (2011)).
- Evaluation of GPS movement data of persons, deliberately collected with mobile devices (e.g., smartwatch, bicycle computer, pedometer, . . .) with the associated medical and physiological data.
- Evaluation of traffic flow data (e.g., applying pattern recognition from webcams).
- Analysis of text documents about semantic similarity (or co-authoring, plagiarism) (Reinhardt et al. 2012).
- Pattern recognition within pictures and videos (e.g., images of drones, NAO-face recognition: see Schäfer and Schlee (2014)).
- Analysis of weather data (<https://openweathermap.org>).
- International projects concerning astronomical and physical satellite data (e.g., MyNASADATA: <https://mynasadata.larc.nasa.gov/students/>).

Data Science Education Curricula

Overall the above discussed orientation of curriculum towards data life cycle models and project does not mean that these curricula are to a huge part or overwhelmingly project based. For example, Grillenberger and Romeike (2018) present a structure for a data science curriculum that is organized in alignment to the NCTM mathematics standards and standards proposal from the German Informatics Society, that distinguish between content areas and process areas.

In academic degree programs typically, basics of the above outlined data operations are taught, and then also some small projects are conducted.

These basics often include, according to an overview conducted by Song and Zhu (2016), the following courses in a bachelor degree: Probability and Statistics, Data Mining, Programming, Discrete Mathematics, Data Structure and Algorithms, Database, and Machine Learning.

School curricula in data science are usually oriented towards data literacy. From the perspective of media and communication, Pangrazio and Selwyn (2019) distinguish four approaches to data literacy: (1) data safety and data management, (2) data science, (3) data hacking, and (4) media literacy approaches to personal data – thereby unfolding a critical view on data science as contributing to data literacy.
